IN reference to the note by Mr. H. E. Molyneux on page 413, have those of your readers who have hitherto been disappointed with *Frau Karl Druschki* as a bedder ever tried the plan of annual lifting? With me it is a great success, and I still think it the best of all the snow white Roses for massing. The plants should be lifted early in November, their roots trimmed back, and also the growths shortened to about two feet, then replanted in the same position or in a new place if preferred. Do not over-mature this Rose and there will be a glorious display of bloom next summer. Of course, it is best to do this lifting right from the commencement; that is to say, after plants have been established twelve months, lift them again; but it may be carried out even with plants established three or four years. Another important point is to secure the plants on the seedling Briar stock. The *Manetti* is a hateful stock, for it and the Briar cutting produce the growths far too rank. Apart from *Frau Karl Druschki* there are no pure white Roses to surpass Mrs. *Herbert Stevens* and *Molly Sharman Crawford*, and after due consideration I give my preference to Mrs. *H. Stevens*. It is true it is inclined to droop; but in late summer the plants send up grand basal shoots that are fairly erect. There are numbers of Roses that have a white effect in the mass, such as Mrs. *D. McKee*, but they are not pure white, and there is still room for a good snow white bedder. I think we have it in Messrs. *S. McGredy's Florence Forrester*. This is a grand Rose as I saw it at *Portadown* recently, and, I should say, far superior to Mrs. *Andrew Carnegie* in texture of petal. In spite of Mr. Molyneux's remark about *Sumburst*, I would advise all your readers to have it, for it is a "great" Rose, and if it gives some whitish flowers early, are they not of exquisite form and substance? I have just cut a bloom of *Sumburst* from a shot-out bud of this year's working that rivalled any golden Rose seen this year, and this not of my own opinion, but of many experts who saw the bloom. **W. E.**

SOME GOOD LATE-FLOWERING, DARK-COLOURED ROSES.

WITH the present abundance of light-coloured Teas and Hybrid Teas, also such grand autumnal pinks from the Hybrid Perpetuals as Mrs. *John Laing*, Mrs. *R. G. Sharman Crawford* and the invaluable white *Frau Karl Druschki*, we are in need of a few extra dark flowers as a complete contrast. The following are half-a-dozen varieties that I can confidently recommend for late use, although all of them are also good throughout the season. *Victor Hugo* will take a lot of beating for many years to come yet, and it has been with us almost thirty years (1884). A very glowing and brilliant crimson, shaded with maroon and purple. Always of good form, holds its foliage well and thoroughly appreciates liberal treatment. This is quite one of the best from the many good Roses *M. Schwartz* has given us. *Ben Cant* favours this variety rather, but is not so deep and clear in its maroon shadings. It is, however, a much stronger grower and very sweetly scented, also a gold medal winner. *Fisher Holmes* has been a prime favourite of mine for many years. It was given to us as long ago as 1865, and only the other day one of the greatest Rose-growers asked me what

could beat it as an all-round dark variety. A very beautifully-formed flower, both early and late, sweet scented, a capital grower, and one that lasts well. Mme. Victor Verdier is another old friend of mine (1803). A clear crimson of beautiful form, exquisite perfume and always a good autumnal sort when well established. These four belong to the Hybrid Perpetual section, and when grown upon the Briar stock in any form are to be preferred as late bloomers to plants upon the Manetti or on their own roots. J. B. Clark, a gold medal Hybrid Tea, comes better in the autumn than at any other time with me. It is a large, well-formed flower of the deepest scarlet, shaded with blackish crimson and carrying a rich, Plum-like bloom upon the petals. A very vigorous grower and quite distinct. Château de Clos Vougeot is a tree but rather erratic grower. Flowers a deep velvety scarlet of great intensity, shaded with a clear, fiery red. As the bloom ages it comes a dark velvety crimson and maroon. The best dark Rose to stand sun that I am acquainted with. It never burns. A. P.

GRAFTING TREES AND SHRUBS.

WHILE most trees and shrubs thrive on their own roots, and may be propagated by seeds, cuttings or layering, there are a few which, for various reasons, it is necessary to bud or graft. This is particularly the case with varieties which do not produce seeds, or do not reproduce themselves true from seeds even when seed ripens. Waterer's Scarlet Oak, *Quercus coccinea* variety *splendens*, may be cited as an example. This also will not root from cuttings, and as layering requires ample material to peg the layers down, the usual method of propagating this and other Oaks is by grafting. While every gardener should be thoroughly conversant

with the art and craft of grafting, it is possible to carry the practice too far, e.g., to graft good sorts of Lilac, using the Privet as a stock, when layering forms a ready means of increasing them, and they will also root from cuttings. In Continental nurseries, grafting is a very popular method of propagation, it being, in many instances, a more rapid method of increase than either cuttings or budding.

In large tree and shrub nurseries, grafting under glass proceeds almost without interruption throughout the year, with, of course, a very busy season from January to April. This is not surprising when we consider the vast number and great variety of trees and shrubs grown in a representative collection.

THE RHODODENDRON AND OAK GRAFTED AND TIED IN POSITION.

A RHODODENDRON STOCK PREPARED FOR GRAFTING IN A POT, WITH UNPREPARED SCION ON THE LEFT AND PREPARED SCION ON THE RIGHT.

and scarce sorts, some of the young growths made during the past summer may be utilised, and a period of six months gained. The common purple Rhododendron, *R. ponticum*, is the stock usually favoured, though, if available, the variety Cunningham's White may be employed. For the more tender indoor sorts, the Himalayan species, *R. arboreum*, is used. To graft a large percentage of stocks successfully is no mean undertaking. In addition to a sharp knife, a suitable stock and scion, it requires considerable skill, which is only obtained by practice, to cut and fit the stock and scion together correctly, afterwards tying them in. For grafting under glass, the stocks should have been potted up some time previously, and be established in the pots. The scions should only be taken from healthy trees. There are several styles or methods of grafting, two of the most important—splice or whip grafting and side-grafting—being illustrated. It is desirable to have the wood of the stock and scion about the same size; but when this cannot be secured, the scion must be placed on one side of the cut, so that the cambium of both stock and scion comes in contact on one side. If a small scion be placed in the centre of a large stock, no union can take place, as the inner woods never unite. In the large illustration an Oak stock is shown suitable for grafting, and a second with the top cut off, or headed down (to use a familiar phrase), ready for splice-grafting. The style of grafting illustrated in the case of the Rhododendron is known as side-grafting. In this the scion is placed on the side, leaving a portion of the growth of the stock to draw up the sap. This method is also adopted for Oaks, being quite as satisfactory as the splice or whip grafting, and is even more successful when the scion is smaller than the stock. After fixing in position, tie the stock and scion firmly with raffia or other suitable material. To hold the scion in position more securely, particularly when it is smaller than the stock, a little tongue is made at the base of the cut on the stock, into which the bottom of the scion will fit. Under glass, in a close frame, it is not necessary to use grafting wax or clay to exclude air from the union

AN OAK STOCK ON THE LEFT, WITH THE SAME CUT DOWN READY FOR GRAFTING ON THE RIGHT. THE SCION IN THE CENTRE IS PREPARED READY FOR FIXING TO THE STOCK.

Under glass also the proper period for grafting is more or less elastic within a reasonable time, and can be done when sufficient wood is available for scions, which is generally the most important consideration with new trees and shrubs. The month of September and early October are preferred by many growers to early spring for grafting Oaks, a larger percentage of successes being obtained. The Oak or *Quercus* family is such a large one that no one kind of stock can be found to suit them all. The common Oak, *Quercus pedunculata*, is, naturally, largely used; but for the American Oaks, the Red Oak, *Q. rubra*, is more suitable. Then, for the evergreen species and varieties, the Holm Oak, *Q. ilex*, or the Turkey Oak, *Q. Cerris*, should be used.

A few Rhododendrons graft more satisfactorily in autumn than spring, notably *R. campylocarpum* and its hybrids or varieties. In the case of new

and prevent loss of moisture. It is very desirable to place on the graft as soon as the stock is cut, and not allow the sap to dry. In due course it will be noticed that a "callus" is forming round the edge of the scion where it touches the stock. The tying material must then be removed and retied less tightly. A considerable number of conifers and Yews are also grafted in autumn, the general rule being to use the common and easily-grown species of the genus as a stock for the rarer species and varieties.

THE FLOWER GARDEN.

THE CAMPANULAS OR BELL-FLOWERS.

(Continued from page 446.)

C. caucasica.—According to the late Mr. George Nicholson, this is distinct from *C. sibirica*, to which *C. caucasica* is referred by the "Index Kewensis." Probably the real *C. caucasica* appears in a recent catalogue as a new plant. It should be between six inches and nine inches high, and have blue, drooping flowers in small clusters in July. Loam, sand and grit, or the moraine or wall.

C. cenisia.—Everyone who has tried this admits that it is a troublesome species, though charming in June with its open cups of brilliant blue. It comes near *C. Allioni*, and is a plant for the moraine. It is lovely there, as those who have seen Mr. Reginald Farrer's plants can well testify.

C. collina.—One of the best of its class and taking after *C. barbata*, but differing in its tree growth and perennial nature. The absence of the beard makes it less attractive than *C. barbata*, but in other respects it is better. The large bells, opening in May or June, are of a fine violet blue. It is about a foot high, and can be grown well even in the border in ordinary soil.

C. colorata.—I am not aware that this Campanula is in commerce, but it seems to matter little, as it is only half-hardy. It comes from the Sikkim Highlands, and has its blue flowers in terminal and axillary racemes.

C. cristallocalyx.—This is practically a poor form of *C. persicifolia*, only included among the rock species because it is often offered as such. I see nothing in it to recommend. The flowers are small and the plant not worth growing. June and July.

C. cymbalaria.—A scarce and neat June-blooming alpine species about six inches high, with pleasing blue flowers. Suited for the moraine or the dry rock garden. Division or seeds.

C. dasycarpa.—Another rare little Campanula some four inches or so high, and with pretty blue flowers in June and July. A moraine or rock plant for leaf-soil and sand. Seeds or division.

C. elatines.—A very charming little Bell-flower, some six inches high, with branching stems of starry blue flowers from June to August. Sunny crevices or the moraine. Division or seeds.

C. elatinoides.—This much resembles the foregoing and blooms at the same time, but is taller. Both are very attractive to slugs, and are difficult subjects save on the moraine.

C. Erinus.—Authorities agree that the true *C. Erinus* is a poor annual, but the plant known in gardens as such is a dainty little June and July flowering, dwarf *garganica*-like species, but infinitely more refined. It has pleasing blue flowers. There

is a lovely white variety, *albus*. Division. Best in dry rockeries, moraine, or wall.

C. excelsa.—This is a queer little dwarf Bell-flower only a few inches high, and having little flowers, opening in June, which look as if a bit had been eaten out of each segment. It is a troublesome plant except in the moraine, and nowhere does it seem to thrive so well as at Wennington Hall, where Mrs. Saunders has it in moraines with good soil beneath. Division or seeds. It hates lime.

C. fragilis.—This is one of the same class as *garganica*, grows about six inches high, is of trailing habit, and has pretty light blue flowers from June onwards. It is pleasing in the rockery, moraine, or wall. The white form, *alba*, is very charming. Division.

C. garganica.—Several Campanulas, all blooming from June onwards, might well be included

ROCK AND WATER GARDEN.

SHRUBS FOR THE ROCK GARDEN.

IN submitting the following list of shrubs suitable for growing in the rock garden, there are many excellent shrubs omitted, as well as some included which may not meet with the approval of the readers of THE GARDEN. Possibly others will send lists or state their views regarding the most suitable subjects for this important phase of rock gardening, and thereby help to bring before the gardening public the best selection of plants for the purpose under notice. Few will question the propriety of associating shrubs with alpiners, not only from a spectacular point of view, but also for the beneficial influence they have upon the alpiners themselves. They afford just that amount of shade

CAMPANULA GARGANICA HIRSUTA, A USEFUL VARIETY FOR THE ROCK GARDEN.

among the forms of *C. garganica*, such as *C. Erinus* of gardens, which by some is called *C. g. compacta*. The type has glossy, crenated leaves and blue flowers. *Alba* is a white variety. *Hirsuta* and *b. alba* are forms with pubescent stems and leaves, and less troubled by slugs than the others. Dry rockeries or the moraine or wall. Division, or seeds in the case of the type. *C. fenestellata*, pale blue, looks like a form of *C. garganica*.

C. G. F. Wilson.—This hybrid, between *C. carpatica* or *C. turbinata* and *C. pulloides*, is represented by two forms, both with deep blue semi-pendent flowers. One has yellow and the other, and better variety, green foliage, and they were raised in the same garden. They are only a few inches high and like a gritty soil in the border, rock garden, or the moraine. A little bone-meal is beneficial. Increased by division. June.

S. ARNOTT.

(To be continued.)

so necessary to the welfare of many, as well as providing a measure of protection which may sometimes be the means of tiding a tender subject safely through the winter. And then they add very considerably to the general appearance of the rock garden, imparting a finished and graceful look to what might otherwise appear naked and bare. Drip is, of course, inimical to the welfare of all alpiners; consequently every care must be taken when planting shrubs to so place them that they will not overhang the rock plants. A great deal depends on the size of the rock garden in making a selection of shrubs, as many that are suitable for a large rockery would look quite out of place in one of smaller dimensions. This can to a great extent be obviated by a judicious use of the knife, as the majority of the shrubs included in this list bear pruning quite well; in fact, are benefited by it. Many of the species mentioned contain numerous beautiful varieties, which space

torbids enumerating in detail. The original list totalled eighty-nine species and varieties, and as this had to be reduced to fifty, many beautiful shrubs necessarily had very reluctantly to be scored off. Regarding those enumerated, the greater number are grown for the beautiful flowers they produce, while a limited number are cultivated exclusively on account of their handsome foliage. Among the latter the *Acer*s occupy a prominent place, their finely-cut and beautifully-tinted leaves making them indispensable, while *Enkianthus japonicus*, *Rhus Cotinus* and several others produce charming leaf-colouring in autumn. I have endeavoured to include in the list of flowering shrubs those varieties that will, as far as possible, extend the flowering period throughout the greater part of the year. Such precocious species as *Andromeda floribunda*, *Daphne blagayana*, *Erica carnea* and *Forsythia suspensa* open their blossoms before the snows of winter have melted; while late autumn is made gay with the handsome snowy plumes of *Hydrangea paniculata* and the purple

Lavandula spica, *Ledum Lyoni*, *Linnaea borealis*, *Magnolia grandiflora*, *Muehlenbeckia nana*, *Olearia Haastii*, *Philadelphus* (various), *Pernettya mucronatus*, *Polygala Chamæbuxus*, *Rhus Cotinus*, *Robinia hispida*, *Rosmarinus officinalis*, *Salix* (various), *Santolina incana*, *Skimmia japonica*, *Spartium junceum*, *Spiræa* (various), *Rhododendron* (various), *Tamarix hispida*, *Thymus* (various), *Vaccinium Vitis-idea*, *Veronicas* (various) and *Weigela* (various).

Twelve Evergreen Shrubs.—*Cupressus lawsoniana filifera glauca*, *C. nana*, *Juniperus chinensis aurea*, *J. hibernica*, *J. japonica aurea*, *J. tamariscifolia*, *Retinospora filifera aurea*, *R. obtusa alba*, *R. o. nana aurea*, *R. plumosa argentea*, *Thuja occidentalis minima* and *T. o. pygmaea*.

Ochilucæ. Bridge of Eavn. WILLIAM LITTLE.

A DWARF OX-EYE DAISY.

CHRYSANTHEMUM PALLENS.

THE large and beautiful forms of the Great Ox-eye Daisy, *C. maximum*, are well known in every garden

being of sufficiently neat and attractive habit for the rock garden. One of the smallest is the *Marguerite* of the Alps, *C. alpinum*, a dainty little plant with a cushion of foliage and pretty white flowers throughout the summer. It grows well in poor, stony soil well supplied with moisture, but the slug is its greatest enemy, and many failures with this plant are due to its ravages. W. L.

SAXIFRAGA BURSERIANA.

DOES IT NEED SUN OR SHADE?

A LONG and hearty controversy raged, it may be remembered, in THE GARDEN last spring over the shade-loving propensities of *S. burseriana*. From that controversy I desisted, after a long letter from Mr. Clarence Elliott (to whom I must, it seems, apologise for saying I "took" him to see *S. burseriana*; let me now, then, with equal truth and greater decency, say that I had the delightful honour of escorting him). I desisted, not from any lack of matter for reply, but because I am

humble-minded; and where that great and good man so firmly puts down his feet, I know there is little room for humble ones to tread. None the less, I nursed a belief that my memory was at least as solid on the point as his. Accordingly, I lay low till occasion offered, and then returned for confirmation to the *Sahm Klamm*, by the very same tram which took me and Mr. Elliott there.

The result of all this, then, is that I am able serenely to repeat my original proposition. After a certain amount of sun in the morning, the whole of the *Sahm Klamm* is in the shade of its great walls for the rest of the day. The sunshine which Mr. Elliott remembers was evidently (as he so sweetly suggests) only that due to my own presence—a most pleasant testimony to my photophoric powers. On the further point of the soil there inhabited by *S. burseriana*, Mr. Elliott must really revise his notions of "serec." Let him return to culling *Thlaspi limosella-fofolium* in the *Haut Boréon* to revive his memory of that delicious compound. *S. burseriana*, in the *Sahm Klamm*, is growing in a dense limestone silt (I have said this before; I now say it again, because it *is so*) which at its coarsest only amounts to fine gravel, but is

THE DWARF BUT LONG-LIVED OX-EYE DAISY, *CHRYSANTHEMUM PALLENS.*

usually of a packed consistency and minuteness, scattering in a spray of whitish particles as up comes a plant.

Finally, I must say, for my own part, that *S. burseriana* itself, in my garden, declares the whole discussion to be rather idle. Mr. Hornbrook (I think it was) so rightly protested against the vain pedantry of trying exactly to copy natural circumstances under the altered conditions of the garden. All one can say—all, at least, that I will positively say—is that *S. burseriana* has the very strongest objection to being parched or frizzled. Apart from that, if the plant has an adequate supply of water, overhead, underground and in the air, I do not here find the slightest difference, either in health or floriferousness, between specimens grown in shade or in the fullest sun. The shadow of a great rock would, no doubt, much avail it in a thirsty land; but sound drainage, a light,

spikes of the *Buddleias*, such as *Veitchii* and *magnifica*. In addition to the flowering shrubs, I append a list of twelve dwarf evergreens, which will be found especially interesting during the winter months, when the majority of the others have shed their foliage.

Fifty Suitable Shrubs.—*Acer palmatum* (various), *Andromeda* (various), *Arctostaphylos Uva-ursi*, *Azaleas* (various), *Berberis* (various), *Bryanthus empetriformis*, *Buddleias* (various), *Cistus* (various), *Comptonia asplenifolia*, *Cotoneaster* (various), *Cytisus* (various), *Daboecia polifolia*, *Daphne* (various), *Deutzia* (various), *Enkianthus japonicus*, *Ephedra distachya*, *Erica* (various), *Escallonia langleyensis*, *Eucryphia pinnatifolia*, *Forsythia suspensa*, *Gaultheria procumbens*, *Genista* (various), *Helianthemum* (various), *Hydrangea paniculata grandiflora*, *Hypericum* (various), *Iberis* (various), *Kalmia* (various),

on account of their value as border plants and the beauty and elegance of their flowers. *Chrysanthemum pallens*, the plant here illustrated, belongs to the same group, but it is of a more perennial character. Unlike *C. maximum*, which is a short-lived plant, this species, which is found over the greater part of Middle and Southern Europe, comes up year after year and flowers freely. It has been in the same position and undisturbed for many years. Compared with the other, the flowers may be a little smaller, but what they lack in size is made up for in elegance and number. It is quite a desirable plant for the rock garden, especially when grown in poor soil so that there is no chance of it growing too luxuriantly. It is of erect habit, the flowers being held up well on stiff stems, a great advantage when used as cut flowers. The members of this large family are mainly border plants, few of them

limy loam (with chips and rubble) and a position securing it from being baked beyond endurance, should surely go far towards ensuring the prosperity of this really very easy-going and happy-natured plant. Indeed, I find it hard to understand the halo of doubt and difficulty that seems to encompass *S. burseriana* in the minds of cultivators. Can it, perhaps, arise from excess of precaution—a vicious circle, care begetting failure, and failure care? I have seen so many sad and sickly burserianas, cossetted as the apple of a one-eyed gardener's eye, yet all the more moribund and decrepit in their special pocket or particular fat, hard mixture of soil. But I believe, from watching the plant and collecting its very fine roots, that freedom is its essential want—a quite light, loose mixture of loam and lime and rubble, with perfect drainage down below and a sufficiency of water for its roots. Procure it these, then I would almost premise that in most parts of the country *S. burseriana* could boldly be packed into any sort of reasonable place with no more regard or fuss (and all the better without it), and there stay forgotten until its astonishing eruption of white moons recalls the plant to your memory in the darkest days of the year.

REGINALD FARRER.

TREES & SHRUBS.

A BEAUTIFUL WALL SHRUB.

CEANOTHUS THYRSIFLORUS.

CEANOTHUSES are becoming more and more popular among flowering shrubs for clothing bare walls. The flowers are not large, it is true, but this is more than compensated for by the great profusion of inflorescences bearing small flowers. There is a well-known variety of *Ceanothus azureus* known as *Gloire de Versailles*. It is a most desirable wall plant, flowering in April and May. *C. thyrsiflorus* comes into flower a little later, and is seen at its best in the early days of June, when it forms a suitable companion to *Wistaria multijuga* for a wall or verandah, the two flowering together at that time. In the accompanying illustration this *Ceanothus* is seen trained on a sunny wall in Mrs. Godfrey Pearse's garden at Taplow, Bucks. The plant illustrated is some 25 feet or 30 feet in height, and it continues to grow and flower freely in this warm soil and sunny position. Most of the *Ceanothuses* are natives of warmer climes than our own, a fact that should not be overlooked at planting-time, although they often give a good account of themselves when grown in a northern aspect. A warm soil over a well-drained subsoil is necessary for the successful cultivation of these beautiful wall shrubs.

WHAT IS A FLORIST'S FLOWER?

(Continued from page 463.)

ONE generally forms some impression, right or wrong, of an author from his book; and after reading "Daffodils" I seem to gather that Mr. Jacob, while he looks for the advent of a dictator, would himself possibly prove a restive subject to the potentate he sighs for. The author of "Daffodils" has himself, I fancy, too catholic a sense of beauty

shows," which would seem to imply that two standard features have been already fixed, and that, unless a flower shows a red eye and overlapping segments, capable judges will rule it out of court. Of course, it is not so, and let us hope it never will be so, but that judges when they enter a show-room will keep an open mind and allow every form of beauty its proper value. I myself can, I hope, as much as anyone admire broad, overlapping segments and a deep red eye; but I am not sure that the Daffodils I admire most have either the one feature or the other; indeed, I am pretty certain they have not. After all, what is there so inherently and exclusively beautiful in overlapping segments? Is it not conceivable that a star-shaped flower, in which the segments meet only at the base, might be just as handsome in its own way as *Cossack*? As an instance in point I would name that good old variety, *Maximus*, the perianth segments of which are relatively long, narrow, tapering and twisted, each of which characteristics, so far from being a blemish, is a beauty. To alter any one of them would be to change the flower for the worse. *Maximus*, of course, has no "deep red eye," but it has what is quite as good. I will cite Mr. Jacob fifty Daffodils the redness of whose eyes leaves nothing to be desired if he will name me half-a-dozen with the rich yellow body-colour of *Maximus*. I know only one—*Santa Maria*, a poor flower in all respects other than colour, and not in the running with *Maximus*. As for the much-prized red eye, it is not profane, I hope, to suggest that raisers are possibly overdoing their enthusiasm for the red eye. Still, I too have been in *Arcadia*, and know the thrill of the "red eye." I would fain hope, nevertheless, that no redness of eye, however brilliant, will be held to condone faults of form, colour and constitution, as in the case of that once (and possibly still) much-esteemed flower, *C. J. Backhouse*, which has a beautiful red cup, but is otherwise worthless. By all means let judges give full value to red eyes and overlapping perianth segments when they see specimens of these that please them, but equally let them refrain from creating cast-iron regulations as to the form of segments or the colour of eyes or other features in which the Daffodil

CEANOTHUS THYRSIFLORUS CLOTHING A WALL IN A BUCKINGHAMSHIRE GARDEN.

ever to make a sound florist of the Glenny school I have no doubt that Mr. Glenny could have given Mr. Jacob half-a-dozen excellent reasons for relegating Frank Miles to the refuse-heap; but one likes to think that Mr. Jacob could (and would) have given Mr. Glenny a round dozen of reasons for allowing that Daffodil to remain where it is in his border. Still, there can be no doubt that Mr. Jacob, when his judgment is at its least robust, has decided hankerings after the flesh-pots. "Its round overlapping perianth," he says, speaking of *Cossack*, "and its beautiful deep red eye are just what judges like to see at

displays such an infinite variety. Let us not, in short, kick the Daffodil upstairs. But, after all, am I not vexing my soul without a cause? For I do not believe there are any florist's flowers nowadays—not as Glenny understood the term. Could that esteemed gentleman re-visit the showrooms which in his life he so much adored, he would be unpleasantly nonplussed and disconcerted to see how little is made nowadays of the flowers for which he drew up such a drastic code. Auricula-growers no doubt he could find if he searched them out, who would show him flowers which he could recognise. But imagine the

consternation of the poor old gentleman could he have put in an appearance at the late Chelsea Show and seen the Tulips—the Cottage Tulips, the Darwins, the Parrots, and other Tulip profanities! "Where," he would ask in his obsolete dialect, "are the Bizarres and the Byblœmens?" And nobody except Mr. Jacob would understand him; and he would lead the venerable shade to an obscure annexe, a sort of side-show, hidden away as it it were ashamed of itself, and there the ghost of the old florist would see a few, a very few, Tulips of the kind he used to know, lovely flowers, too, streaked and flamed and feathered according to the orthodox patterns approved in his day and generation. Then possibly (no doubt to Mr. Jacob's sensible relief) the spirit would ask to be taken to the Carnations. Peradventure, though they have outraged the Tulip, they will have spared the Carnation. So once again they make their

scents the morning air; yet, ere I hie me hence once more to purging fires, one thing I'll whisper in your ear: Florist's flowers you no longer possess, nor florists either. Better things you may have, only not these, not as I knew them. Adieu, my friend, adieu. I'll see you by and by, when you have done with Daffodils!"

SOMERSET.

THE KITCHEN GARDEN.

THE OUTDOOR MUSHROOM-BED.

THE present is a good time for the making-up of a Mushroom-bed in the open air. Many amateur gardeners think it is really necessary to have specially-constructed houses in order to be successful in the cultivation of Mushrooms. The latter may be easily grown in cellars and ordinary sheds, also in the open air,

placed thuly on the floor of an open shed, or in the open air altogether if the weather is dry and fine, and thrown into a heap for two days prior to being laid in thin layers and well beaten down in the bed itself. A bed of useful size is one made on a foundation 3 feet 6 inches wide and 8 feet long. The height will be governed by the width, and should be about two feet six inches or so. Insert the lumps of spawn 2 inches deep and 10 inches apart every way all over the bed; then cover the latter with a layer of sifted maiden loam 2 inches thick, making the surface smooth with the back of a clean spade. Do not give any water, as the natural steam in the bed will provide sufficient. Cover with clean litter neatly put on a foot thick; then thatch the whole bed with straight straw laid on 2 inches thick. The cultivation of Mushrooms is interesting work, and is unlike the culture of any other garden crop. Mushrooms should appear in seven to eight weeks from the date of spawning, and when gathered in open weather care must be taken not to expose much of the surface of the bed at one time. Later on, beds may be made wholly of tree leaves where they are very plentiful. To commence with fertile spawn is just as important in the successful cultivation of Mushrooms as good seed is in growing flowering plants. Spawn should, therefore, only be procured from a reliable source, for after a while, and especially if not properly stored, the spawn loses its vitality.

SHAMROCK.

THE NEW ASTER FELTHAM BLUE. A USEFUL VARIETY FOR THE HERBACEOUS BORDER.

way through the perspiring crowd, the subtle essence of the Glenny shadow fitting easily by the side of his conductor's substance, until they pause before the monumental display of Mr. C. Engelmann. Helplessly the perturbed spectre eyes the wilderness of blossom. These massive, leggy blooms are not the flowers for which erstwhile he formulated laws. Yet even the ghost of Mr. Glenny retains some spark of his terrestrial fire, and, bewildered as he is, the poor, disoriented shade can scarce forbear to clap his spectral palms: vases of Sunstar and Benora, banks of White Wonder and Pioneer, columns of Lady Northcliffe, waterfalls of White Enchantress and Electra! "Magnificent!" he mutters, "magnificent! But, you know, not quite according to Cooker! Where are the dapper little smooth-edged flowers on discs of white paper—the flakes and bizarres that once delighted Lord and Simonde? A glorious sight, my friend, though—but soft! methinks I

provided they are protected from the excessive rains and severe frosts by thick coverings of clean litter and mats.

A Good Position may be found on the north side of a fence, wall, or building. If the latter be high, of the height of a dwelling-house, build the bed quite 12 feet away from it to the north. Do not build directly under the branches of trees, as the water dripping on the bed will tend to chill it.

The Material and Size of Bed.—It is not necessary to have horse-manure solely. If half is horse-manure and half clean tree leaves, material of a gently-heating nature will be obtained. A fair quantity of litter should be left with the manure, as the latter is liable to burn through overheating if employed alone. The inclusion of tree leaves not only prevents too high a temperature, but steadies and prolongs it. Before the ingredients are put together to form the bed, they must be

in branching inflorescences, are of a clear azure blue. Shown by Mr. C. Turner, Slough.

Dahlia Inchmarnock.—This is one of the most pleasing of the Collarlet Dahlias we have yet seen. The ray florets are salmon scarlet, and the inner florets of sulphur yellow. The flowers are small, neat and freely borne. Shown by Messrs. Dobbie and Co., Edinburgh.

Odontioda Seymouria Orchidhurst variety.—This is derived from the intercrossing of *Odontioda Charlesworthii* and *Odontioda Bradshawia*, and may be described as a fine scarlet form of the first-named parent, of excellent shape and substance.

Lælio-Cattleya George Woodhams.—A fine hybrid obtained by intercrossing *L. purpurata* and *C. hardyana*. The sepals and petals are purplish magenta, and the large lip deep crimson. Both were exhibited by Messrs. Armstrong and Brown, Tunbridge Wells.

NEW AND RARE PLANTS.

AWARDS OF MERIT.

Aster Feltham Blue.—The merits of this variety as a border flower are already recognised (see illustration). It is of medium height, of branching habit and profusely flowered. The flowers are of a pleasing shade of lavender blue. Shown by Messrs. T. S. Ware, Limited.

Salvia uliginosa.—An interesting species, native of the marshlands and river banks of Brazil. Despite its habitat, it is said to be a hardy perennial in this country. The flowers, somewhat sparsely borne

GARDENING FOR BEGINNERS.

ROOTING CUTTINGS UNDER HAND-LIGHTS.

HAND-LIGHTS form an almost indispensable adjunct to every garden. The beginner will find them most useful to root cuttings of hardy and half-hardy plants. The usual sizes of the hand-lights are 15 inches and 18 inches square. The cloches used so much in French gardening may also be used for rooting cuttings of Pentstemons, Violas, Calceolarias and other similar plants, but they are not so handy and convenient as hand-lights.

The first item to consider is the preparation of a bed of sandy soil in which to insert the cuttings. Choose a warm, sheltered border as the spot on which to make the bed, to avoid the necessity of providing a large quantity of protection for the hand-lights during cold, frosty weather. Make the bed of sandy soil firm, and over it spread a thin layer of silver sand. Keep this dry, so that when a hole is made with a dibber and the cutting inserted, the sand will trickle in round the cutting and fill up the hole. Mark out the size of the bottom of the hand-light by standing the frame on the sand. The cuttings are more readily inserted before the hand-light is finally placed in position. Some hand-lights are made in two parts, a bottom and a top; these cost slightly more than those made all in one, but they are much more convenient. Having inserted the cuttings, stand the bottom of the hand-light over them, and give a good watering with a fine-rosed watering-can to settle the sand round the cuttings and prevent them flagging. Keep the frame close till the cuttings are rooted, shading whenever the sun shows signs of gaining power. As time proceeds the cuttings will root, and then air must be gradually admitted and the amount

of shading lessened, finally dispensing with it entirely. It is not necessary to limit each hand-light to one kind of plant, Pentstemons, for instance. These, with cuttings of hardy Fuchsias and Veronicas, may be inserted in a single hand-light. Choose in all cases short-jointed, healthy shoots for cuttings. The length of the cuttings will depend a little on the kind of plant; cuttings of Violas, for instance, will not be so long as those of Pentstemons. An average length of 1½ inches to 3 inches is a convenient size. The distance apart is another elastic point which may rest largely with the grower; 2 inches apart in the rows and 3 inches between the rows of cuttings will suffice, but a little either way will not matter. When once inserted and covered with hand-lights, the cuttings will not require much attention beyond shading from sun. Examine them about once a week to see if water is required, and remove all dead and decaying leaves.

Pentstemons.—The Pentstemon is essentially a plant for the beginner and the small grower with little accommodation. It is easy to propagate, and the plants thrive and flower freely in most soils and situations. Seeds and cuttings are the recognised methods of increase, the seeds being sown in a heated greenhouse during February or early March, and in a cold frame about July. Towards the end of September or early in October is a good time to insert Pentstemon cuttings. The race of Pentstemons most largely cultivated in gardens are hybrids, and comprise a considerable variety of colours. Anyone raising a batch of seedlings last spring will have an attractive display of flowers at the present time. It is worth while taking cuttings of the best of these, presuming the strain is a good one, for as a rule some of the seedlings almost, if not quite, equal the named sorts. Cuttings should also be inserted of the named varieties, as the old plants will only survive the winter outside in very favoured localities. A list of named sorts would serve no useful purpose here; they are so numerous that one can soon make a selection from a florist's catalogue.

A BED OF SANDY SOIL, WITH SOME CUTTINGS PLANTED AND OTHERS READY FOR INSERTION.

Three sorts, however, call for special mention, and should be in every collection. They are *Crimson Gem*, a very large, rich crimson-scarlet flower; *Southgate Gem*, bright scarlet blooms of medium size, produced in profusion, a hybrid between *Newbury Gem* and a large-flowering florist's sort; and *Newbury Gem*, a fine old Pentstemon producing an abundance of small red flowers. It is also known as *P. Hartwegii*. The making of the cuttings of Pentstemons and their treatment are similar to that afforded to Calceolarias and dealt with earlier in these notes.

Bedding Calceolarias.—For summer bedding the yellow and dark red shrubby Calceolarias are unsurpassed in the cottage and small suburban garden. Late September and early October is the season to insert cuttings to obtain plants for next summer's display. Dibbled in sandy soil 2 inches apart and covered with a hand-light, the cuttings will root and not require much attention till the end of February. Look over the cuttings once a week to remove damp and decaying leaves. Protect from frost with a covering of litter, *Braeken*, or the old stems of *Michaelmas Daisies*. When rooted, which will probably be in about six weeks, air must be gradually admitted by turning round the top of the hand-light a little, closing it up again on cold, frosty nights. Plenty of side growths suitable for cuttings will be found on most of the Calceolaria plants at the present time. Take off the shoots about three inches long, cut through the stem just below a pair of leaves to make a base for the cutting, removing two, or possibly four, leaves. As soon as inserted, water in and close up the hand-light. To obtain sturdy, bushy plants, the points or growing tips of the young plants should be removed in early spring. This will induce each plant to make two shoots, possibly more. Half-a-dozen of the best sorts are *Golden Gem*, rich yellow; *Camden Hero*, dark red-brown; *The Sultan*, very dark reddish crimson; *Prince of Orange*, bronzy yellow; *Cloth of Gold*, golden yellow; and *Bijou*, bronzy crimson. Calceolarias delight in a moist, fairly rich soil, and a half-shady border is preferable to one in full sun.

CUTTINGS OF VIOLAS AND PENTSTEMONS PLANTED IN SANDY SOIL AND COVERED WITH A HAND-LIGHT. NOTE THE MOVABLE TOP.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Flower Garden.

Propagation.—This is an operation that still needs attention, and ought not to be deferred too long, or some of the subjects may get touched by frost, when a good strike is much more difficult to secure.

Calceolarias.—The shrubby varieties, for bedding purposes, should be propagated from the soft growths springing from the base of the stem of flowering plants, and the sooner they are, within reason, the more easily will they strike. They may be rooted in pots or boxes; but the best system is to prick them out, 2 inches or 3 inches apart, in a cold frame, using a light, open compost for the purpose, afterwards keeping them sprayed and shaded till the foliage becomes stiff and upright, when they may be treated a little more hardily; and as soon as well rooted they may be given plenty of air during fine weather.

Veronica Andersonii variegata and Marguerites are easily-grown bedding plants that may be propagated now, practically in the same way as advised for Calceolarias.

Lantanas are used a good deal for bedding purposes, and the various varieties root readily if nice soft cuttings are secured and placed singly in 2½-inch pots, using a very light compost. A little bottom-heat is necessary during the rooting period, and if fair-sized plants are desired for next season, the shelf of an intermediate house is a good place on which to winter them.

Chrysanthemums.—Many of the early-flowering section are now making a good show, and in districts which are low-lying and subject to early autumn frosts, some provision should be made for covering them. Pit lights, of course, are useful if placed well above the flowers, and will keep them in good condition for a long time. Tiffany stretched over them at night is also effective, but as this lets the wet through, the lights are to be preferred; or oiled paper, tacked over a light framework, acts almost equally as well. Plants that are to be lifted for flowering indoors should have the roots cut round at a reasonable distance from the stem, and if well watered afterwards and kept sprayed it will prevent them flagging. As soon as the roots commence to run again is the best time to lift the plants and take them indoors.

Plants Under Glass.

Violets.—Preparations should now be made for lifting and planting in the frames. In the first place, the frames should be filled to within a foot of the glass with a compost which is known to suit the plants in the particular locality, this varying in some instances from pure loam to pure leaf-soil.

Chrysanthemums.—By this date many of the earlier varieties will be showing colour, and if of the large-flowering section they should be housed at once, but not before all the foliage has been carefully syringed with a solution of sulphide of potassium to guard against mildew. Decorative varieties, such as Mary Richardson, Mrs. Roots, Heston Bronze and Soleil de Octobre, should also be placed under cover as the flowers show colour. By placing the plants indoors rather early, they sometimes fill up a gap after the outdoor ones are cut down, and, where used, make room for the mid-season and late varieties.

Browallia speciosa.—Though these will have done well up till now in a cool house, they are better for a little warmth from now onwards, an intermediate temperature suiting them well. A little weak liquid manure may be given to plants in bloom, and this should keep them going till well into the autumn.

Euphorbia pulcherrima plants are now well established in their flowering pots, and should be removed from the pit in which they have been growing to a suitable house with a temperature of from 55° to 60° at night. Keep them well sprayed on all fine days, and when the pots are well filled with roots, feed regularly with a mild manure, such as Clay's Fertilizer or a little blood manure, both of which I have found to suit them well.

Euphorbia jacquiniæflora.—Plants of this will take rather more heat than the preceding, and where they can be trained up the wires of a Melon-house

they will ripen their wood well, which is very essential to get a good long spray of blooms.

Shading.—Much of the shading material may be left off now, only the more tender subjects requiring it during the hottest part of the day; but a sharp look-out must be kept if the sun comes out brightly after a few wet or sunless days.

The Kitchen Garden.

Turnips sown during the latter part of August should be thinned to a fair distance apart, so as to allow the foliage to become hard and not so easily damaged by frost. After thinning, hoe well, continuing the operation as often as necessary, so as to facilitate the growth.

Celery.—Continue the earthing of Celery as the weather permits, giving a good watering and feeding to the latest batch a day or so before commencing earthing. The mid-season rows should be finished off carefully, so as to throw off superfluous moisture, especially where the soil is heavy.

Onions.—All Onions should be got under cover as soon as possible, the smaller bulbs being put where they can be bunched or tied in strings during wet weather.

Fruits Under Glass.

Strawberries.—Plants that are well rooted should be watered occasionally with liquid manure; but there is no need to try to get extra-sized crowns, as those that are of moderate size and well ripened, I find, give the best results. Where there is a tendency for the foliage to become mildewed, the plants should be sprayed occasionally with sulphide of potassium.

Vineries.—Muscat Grapes that are quite ripe and still have to be kept some time should be shaded from very bright sunlight. Air must be kept on at all times, but just sufficient heat must be kept in the pipes at night and on dull days to keep the air dry and circulating.

Very Late Grapes that are ripening should be kept a trifle drier, especially towards the evening, and the temperature not allowed to fall below 58° to 60°, though when quite ripe a few degrees lower will keep them in good condition.

THOMAS STEVENSON.

(Head-gardener to E. Mocatta, Esq.)

Woburn Place Gardens, Addlestone, Surrey.

FOR NORTHERN GARDENS.

The Flower Garden.

Propagating Calceolarias.—The old orange yellow Calceolarias of the aurea floribunda type are seldom seen nowadays. Lemon shades are still popular, however, and old amplexicaulis, Lemon Gem and Queen Alexandra are all well worth growing. A start should be made with the propagation of these within the next week or so. The first and last mentioned of the foregoing trio are not quite so hardy as some of the other varieties, so that if the frame in which they are to be wintered is not capable of being slightly heated in time of frost, ample protecting material will have to be provided.

Preparations for Bulb-Planting.—As annuals go out of bloom they should be cleared away, and the ground they occupied should be lightly dressed with decayed vegetable refuse or other manure, and then dug over to be in readiness for the reception of bulbs and other spring-flowering plants.

The Rose Garden.

Selecting Climbers.—We now have such a choice of high-class Roses in the Hybrid Tea section that fewer Roses are now grown on walls; but pergolas, pillars, arches and screen fences clothed with Rambler Roses are much in evidence, and so far as climbers are concerned, the ramblers fill the popular imagination at the present time. I will therefore confine myself to these at present. For pinks, those making a start cannot do better than plant Dorothy Perkins and Lady Gay, and for a white, White Dorothy Perkins is unsurpassed. Of red shades there is considerable choice. Among singles, Hiawatha is an easy first, but for an early bloomer Carmine Pillar is excellent. Among doubles, Crimson Rambler and Flower of Fairfield are both good. Purple East is an attractive semi-double pillar Rose. Among single pinks or bluish,

Blush Rambler and Euphrosyne are to be commended. Among yellow shades, Alister Stella Gray is the most accommodating.

The Rock Garden.

Colchicums.—These attractive autumn flowers are admirably adapted for the lower reaches of the rockwork, and those who possess them will be enjoying their beauty now that the bulk of the occupants are assuming a rather sombre aspect. Bornmuelleri, speciosum, speciosum album, Parkinsoni, autumnale roseo pleno and a. albo pleno are all worthy of inclusion.

Autumn Crocuses.—These, too, are excellent for brightening up the lower reaches of rockwork. I can only speak of a few of them, but can recommend longiflorus (odorus), speciosus and zonatus. Like the Colchicums, August is the ideal month for planting, but they can be planted with safety immediately after flowering.

Plants Under Glass.

Lilium longiflorum Harrisii.—Both this variety and the type are excellent for conservatory decoration, and for early work the bulbs should be procured and potted up as soon as convenient. Good results can only be had from strong bulbs, and it is bad policy to buy small, cheap ones. Loam, peat, sand, leaf-mould and rotten manure in a rather rough state form an excellent compost for Liliums.

Freesias.—The sooner these are potted up the better. Eight or ten bulbs in a 5-inch pot make a nice display. Use light soil similar to that recommended for Liliums, but in a less lumpy condition. Stand in a cold frame for a time.

Perpetual-Flowering Carnations.—Thrip is sure to appear, and must be kept in check by weekly fumigation until the flowers begin to open. Give abundance of air during the day, with a little over-night unless the weather is very cold.

Fruits Under Glass.

Pruning Early Peaches.—If the trees are completely delatolated, the sooner they are pruned the better. In the case of young, partially-developed trees, the first consideration should be the framework of the tree; but in the case of fully-developed trees, the work of pruning is comparatively simple, and consists chiefly of cutting away the shoot which has just borne fruit and the shortening of the succession shoot which has been laid in, and which is to bear next season's crop. Always cut back to a wood-bud, which is less plump and more elongated than a fruit-bud. The distance from one bearing shoot to another should be about a foot.

Late Figs.—In order to ripen off these satisfactorily, a night temperature of 60° to 65° will be necessary.

The Hardy Fruit Garden.

Preparations for Planting.—Where the planting of fruit trees is contemplated, some suitable soil should be got in readiness in which to give the trees a start. Nothing equals maiden loam, but it is often a scarce commodity. If, however, a quantity of it is procurable, it can be mixed with an equal quantity of road parings, which contain a considerable amount of fibrous material.

Late Stone Fruits.—In the event of frost occurring, any late, unripe Peaches or Plums must be protected with scrim or other light material.

The Vegetable Garden.

Celery.—Continue to earth-up Celery as necessary. Early crops that are receiving their final earthing-up should have the soil brought up to an apex, and it should be beaten with the back of the spade, making a smooth surface to run the water off.

Turnip-Rooted Beet should now be stored. Be careful not to break the roots, or bleeding will ensue, thus greatly spoiling the crop.

Autumn-Sown Onions.—The young seedlings are now well up. Run the Dutch hoe between the rows to kill the seedling weeds and aerate the soil. Weeds growing in the rows must be pulled with the hand.

Kidney Beans.—Store all the surplus yield in salt, as previously directed, before they become tough or get injured by frost. Steep the pods thus treated in fresh water for twelve hours prior to cooking them.

CHARLES COMFORT.

Broomfield Gardens, Davidson's Mains, Midlothian.

DAFFODIL NOTES.

Poetaz Varieties.—The writer of the article on Poetaz Narcissi in the Bull Number of THE GARDEN is not, I fear, very familiar with their history. Every variety mentioned in it was raised by Mr. R. van der Schoot. He has told me about the sudden thought that came to him as he was one day passing by some ornatus in his bulb-fields, and how he at once acted upon it, with the result that all those varieties mentioned, and some others as well, first saw the light of day—now a good many years ago—in his trial grounds at Hullegom. Jaune à Merveille is no newer than the others. It is more expensive, like Sunset, another very lovely yellow Poetaz, because it is such a slow increaser. It is a long time since I bought my first bulbs of this new race from Vilmorin of Paris, and then there was but little difference in the prices of any of them—I suppose because their powers of increase had not been sufficiently tested. Now they are known, and prices are fixed accordingly. Alsace, Aspasia, Elvira, Irene, Jaune à Merveille and Sunset are, in my opinion, the best half-dozen, the first three mentioned having white and the last three yellow perianths. Alsace is the best for early forcing, as it comes so easily and well. Irene is a much softer shade of yellow than either of the other two. I like it exceedingly as a pot plant. Jaune à Merveille, Sunset and Elvira have flatter perianths than any of the others, and on this account are useful for showing. Aspasia is the tallest and most vigorous, and a real everybody's flower. I must say, however, that in its native soil it has not that superiority in vigour and height which it has with me. As far as I know, the only Poetaz in commerce that has been raised by Mr. Engleheart is my favourite Orient, which has an undulating white perianth and a palish yellow cup with a clear red edge. All that I have mentioned are excellent both for pot work and for the garden, so much so that I have no hesitation in following up "A. B.'s" little notice with another puff of this important race.

Daffodils to be Grown in Pots.—Gardeners, like betting people, like "tips," only they do not get them quite so often; but when they do, let us hope they are more reliable. I quite thought there would have been a few about what to buy for pots in the Bull Number. Directly I saw there were none, I wired off to the Editor and begged for a column in next week's edition. The time is getting on now, for potting, at any rate. Before these lines are read and the bulbs procured, it will be high time they were in. Last year I believe I "tipped" Firebrand. I know a lady who has bought some this autumn on my recommendation. If she has any luck at all, she will find I have "tipped" a winner. I have had it for the last three years myself, and it has never been found wanting. Blackwell is another beautiful variety that lends itself to gentle forcing very readily, always keeping a good shape and coming with a fair amount of colour in the cup. Weardale Perfection is more at home in the greenhouse than anywhere else. Now that it is procurable at about two shillings each, half a sovereign for a potful of five would be money well invested, and would bring a certain return in the pleasure it would give anyone who likes refined flowers. I could say almost exactly the same about Lady Margaret Boscawen, only it is just a little less *chic* and gives more idea of massiveness. Of King Alfred it is hardly necessary to speak. When Messrs. James Carter and Co. got hold of the selling of this wonderful flower, they knew what they were

doing. In pots it has no rival among the big yellow trumpets, and I find with care in ripening under glass that pot-grown bulbs do not do so very badly a second year. Orphée is seldom seen in any list nowadays. I hope some firms still have it, for I consider it one of the most satisfactory pot red edgers that we have at a low price. Barrii conspicuus is not in it when flowers are wanted in early February. Lucifer is a good lasting plant under glass, and the colour is retained pretty well until the end. I strongly advise a trial. The Leedsus, as a whole, seem cut out for the purpose I am advocating. Some day the "giants" will be possible to be had at a reasonable figure, and then I expect no one will be without a potful or two. Meanwhile, let me say what a dainty bloom Fairy Queen is. Everyone must like it. Then, it is so free. An old-fashioned Tazetta that appealed very much to me this last spring was Dr. Holland. Mr. Bowles probably does not know it, or it might have been coupled with Bazelman major and Muzart orientalis; or it may be he was writing of outside flowers, whereas I am strictly now an inside man. Lastly, let me advise Mr. Duncan Pearson, and anyone else who is interested in the Poet type, to try, as a good everyday plant, Ben Jonson. I am disposed to think it has been peculiarly well named, for the life-history of the man may well be repeated in the flower; and that the day will come when it will enjoy the high favour of its patrons—the Daffodil-loving public.

JOSEPH JACOB.

DAFFODILS IN NEW ZEALAND.

(Continued from page 464.)

THERE are several large growers in the South, some of whom, including Mr. Charles Goodson of Hawera (Taranaki), Mr. A. E. Lowe of Tai Tapu and Mr. F. Biggs of Christchurch (Canterbury), Mr. A. Miller and Mr. J. Blair of Mornington, Dunedin, Mr. J. J. Woods, Mr. H. Hart and Mr. H. Darton of Lawrence, and Mr. A. B. Haggitt of Invercargill (Otago), have been for some years engaged in raising seedlings, with considerable success. There are, I understand, no growers of seedlings in our capital province (Wellington), though Mr. Thomas Mason of Lower Butt (now deceased) raised some good things, which have, unfortunately, gone astray. All the above-mentioned growers are, I believe, amateurs, with the exception of Mr. Lowe, who is gardener to the Hon. R. Heaton Rhodes (Postmaster-General) of Tai Tapu, Canterbury, and as Mr. Rhodes has been a lavish importer of the best things obtainable in England, in his service Mr. Lowe had exceptional opportunities for hybridising, of which he fully availed himself. As the result he has a very fine lot of seedlings, some of which have received certificates, and he considers several of his raisings to be improvements on standard imported varieties.

We have not seen any of the Southern seedlings in Auckland yet, but we hear of some fine trumpets from both pollen and seed of King Alfred, and also some fine red cups. For the past two seasons we have had the services of Mr. E. A. Hamel of Dunedin as judge at our spring show, and I am indebted to him for some of my information with regard to matters in the South. He

informed me, among other things, that he considered they grew red cups better in the South, getting richer colour of longer standing than he observed in Auckland. This is probably attributable to the cooler climate of Otago, many red-cupped varieties here being given to "burning" quickly in fine weather. I must not omit to refer to the distinction attained by Mr. Biggs of Christchurch of being the first New Zealand grower to exhibit a seedling in England and merit favourable comment from so good a judge as the Rev. J. Jacob, as did his Hon. R. J. Seddon (*vide* your issue of March 20 last).

The subject of nomenclature is now causing some trouble, as, with so many new varieties being raised in Australia and New Zealand, it is but natural that duplication of names should occur. Several names appropriated and used out here during the past few years are now, we find by perusing recent catalogues, &c., borne by novelties recently exhibited or put into commerce at home, and unless some system is devised to regulate the matter, confusion must ensue when Antipodean novelties now being introduced into commerce begin to be distributed. I noticed paragraphs recently in THE GARDEN referring to the probability of a Daffodil Year Book being published, and a movement for the formation of a National Daffodil Society. I think these are both good projects, and that they will receive the approbation and support of New Zealand growers, and I hope one of the subjects they will take in hand and deal with will be this same matter of nomenclature.

Another matter requiring attention here is the certifying of new varieties. I do not know whether the Southern societies have given the matter serious attention, but in the Auckland Horticultural Society it has come up on two or three occasions for discussion; but definite action was deferred, there being a feeling that an award of merit conferred by a society such as our local one would not carry much weight outside, and that a Dominion committee or committees should be constituted for the purpose of adjudicating on new varieties, not only of Daffodils, but all other classes of horticultural products. So far the difficulties to be overcome have prevented the consummation of so desirable an object. Our society, however, felt that some recognition of Professor Thomas' work with the Narcissus should not be longer postponed, and at our 1911 and 1912 shows instructed the judge (from Dunedin) to consider the seedlings exhibited with this object in view. Accordingly, some six or seven of Professor Thomas' productions then in bloom were awarded the Auckland Horticultural Society's certificate of merit, of which, I think, they were well worthy, and it is intended to send particulars of these to the Editor of the Daffodil Year Book.

The cut-flower business here, which a few years back was of small importance, has now developed to very noticeable proportions, and in this the Daffodil takes a foremost place. The flowers are grown for sale mostly by orchardists and nurserymen in the remoter suburbs, planted between the rows of fruit trees, and are found to pay fairly well as a side-line, as they come in at a time when orchard work is somewhat slack, and the returns from them are a welcome prelude to the fruit harvest. Some of the larger growers pack and forward a large quantity to the Southern towns, where enhanced prices are obtained, as our season is considerably earlier than theirs. The best selling kinds are the large yellow trumpets, but most of the large, long-stalked ones find a ready market.

In your issue of December 14 last appeared a paragraph (which was copied by our New Zealand *Graphic*) referring to the possibility of the best and newest of New Zealand raised Daffodils being grown and shown in England. I have been unable to obtain any information locally as to this scheme, so I assume it emanated from one or other of the large Southern growers. We hope the idea will materialise in the near future, and that, if it does, Auckland will be well represented. Of course, growers may not care to send away their very latest productions, of which the number of bulbs would be very limited, and the New Zealand display would be handicapped by the lapse of time necessary to the acclimatising of the bulbs at home, and possibly they may not at first take kindly to the English climate. Still, if they were taken in hand by one or more of your many expert growers, and not staged until they had time to settle down and become "at home" in their new environment, the experiment and opportunity of comparison should prove very interesting, and I venture to think should do us credit.

Since jotting down these notes, I have read your reports of the London and Midland shows, and the accounts of the latest good things make us pause and wonder how much further the "manufacture" of such wonderful new specimens of this flower will go and what direction the next break will take. One wonders what would be the emotions of Dean Herbert, Leeds, Backhouse and other pioneers of half a century and more ago, could they visit a present-day show; for surely they never could have imagined that the work begun by them with such meagre material would develop to the extent it has and bring forth such remarkable forms as are now coming forward each year in increasing number and variety. These latest reports, while making us feel diffident as to how our flowers would compare, yet make us more anxious to know how we stand, and we feel every confidence that our representatives would make a respectable showing, especially if the home critics bear in mind that so far we have had to import all our breeding stock, and we are therefore of necessity some years behind in this important respect.

Auckland, New Zealand. A. E. GRINDROD.

TRIALS OF ANTIRRHINUMS AT WISLEY.

As announced in our issue for September 6, the Royal Horticultural Society have held trials of Antirrhinums at Wisley this year. These were visited by the floral committee on the 29th ult., and the following awards made by them on that occasion were confirmed by the Council on the 9th inst.:

Awards of Merit.—To Amber Queen, from Messrs. Barr, Covent Garden, and Messrs. Watkins and Simpson, Covent Garden; Beacon, from Messrs. James Veitch and Sons, Chelsea; Beauty, from Messrs. Barr, Covent Garden; Bonfire, from Messrs. Simpson, Birmingham, and Robert Sydenham, Limited, Birmingham; Carmine Queen, from Messrs. Watkins and Simpson, Covent Garden; Cocinea, Crimson King and Daphne, from Messrs. Hurst, Houndsditch; Defiance and Fire King, from Messrs. Bath, Wisbech; Golden Morn, from Messrs. Watkins and Simpson, Covent Garden; Golden Queen, from Messrs. Bath, Wisbech; Maize Queen and Moonlight, from Messrs. Dobbie, Edinburgh; Pink and Queen Victoria, from Messrs. James Veitch and Sons, Chelsea; Rosy Morn,

from Messrs. Watkins and Simpson, Covent Garden; Salmon Pink, from Messrs. R. Veitch, Exeter; Sunset, from Messrs. Dickson and Robinson, Manchester; White Beauty and White Queen, from Messrs. Dobbie, Edinburgh; Yellow, from Messrs. James Veitch and Sons, Chelsea; Yellow King, from Messrs. Barr, Covent Garden; and Yellow Queen, from Messrs. Hurst, Houndsditch.

Highly Commended.—To Albino, from Mr. F. C. Heinemann, Erfurt; Brilliant, from Messrs. Barr, Covent Garden; Brilliant Rose, from Messrs. Bath, Wisbech; Buft Queen, from Messrs. Watkins and Simpson, Covent Garden; Coral Red, from Messrs. James Veitch and Sons, Chelsea; Dainty, from Messrs. Dickson and Robinson, Manchester; Dainty Queen, from Robert Sydenham, Limited, Birmingham; Firelight, from Messrs. Bath, Wisbech; Galatea, from Messrs. Barr, Covent Garden; Nobile, from Messrs. Hurst, Houndsditch; Pink Beauty and Pink Queen, from Messrs. Watkins and Simpson, Covent Garden; Rosenn, from Messrs. Carter, Raynes Park; Scarlet Carmine, from Messrs. ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—*The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.*

FLOWER GARDEN.

WATER LILIES (Various).—These will succeed much better if you will lay a circle of bricks on the bottom of the tank 12 feet in diameter, and fill up the space with good soil and plunge the baskets in it. The best time to plant out is the end of March or the first week in April; but as you have the plants already by you, put them in water (in baskets) now and add the extra soil in spring.

PLANTING FOR EFFECT (York).—A mass of shrubs with coloured or variegated leaves would answer as well as anything in the position you describe, providing such subjects are selected as may be expected to retain their colour throughout the summer. For late winter and early spring an effect might be made beneath the shrubs by the use of Snowdrops, Crocuses, Winter Aconites, Chionodoxas, or other similar plants. The following shrubs are likely to prove suitable: Prunus pissardi, Purple-leaved Nut, Acer palmatum var. atropurpureum, Cornus alba Spirithii, Acer Negundo californica aurea, Catalpa lignonoides aurea, Eucalyptus japonicus aureus, Cornus alba variegata, C. Mas variegata, Acer Negundo variegata, Cotton Lavender, Golden and Silver leaved Hollies, and Golden and Silver leaved Tree Ivies.

TREATMENT OF BORDER CARNATIONS (H. J. F.).—Under the conditions named we should advise you to pot up your Carnations during the winter and plant them out in the spring. This will enable you to thoroughly clean the place and prepare the soil for their reception. Pots from 3½ inches to 4 inches in diameter are very suitable for the cuttings, and these pots should be quite clean and effectually drained with a broken crock or two placed in the bottom. In potting, instead of sifted soil from the garden, use some good loam, which may be obtained from any local nurseryman. It should be well broken up, but not sifted, and in potting, a few of the rougher portions may be placed in the bottom immediately over the crocks. The other ingredients can remain the same. From your note we gather that the frame is not large enough to accommodate all your layers when potted singly, and if this is the case, the better way will be to give the weaker ones the protection of a frame and plunge

the stronger growers out of doors in Cocoanut refuse, ashes, or some other suitable material. The pots should be plunged to the rims. In the case of those in the frame, it must be borne in mind that plenty of air is essential, the main use of the frame being to keep off heavy rains and to protect from severe frost. While sufficient water should be given to keep the soil moderately moist, an excess must be strictly guarded against.

MOULD ON SOIL FOR DAFFODILS (H. W. K.).—The mould is probably caused by the bones, as you consider, but we do not think that it is likely to do harm to your bulbs. It will be safer, however, to examine one or two of the plunged pots to see if it is present there also, and, if so, if it has permeated the soil, or if it is only on the surface. If it has permeated the whole soil, it will be necessary to repot in fresh compost, using bones which have been properly steamed. We have had this mould on the surface of pots of bulbs occasionally without any detriment to the Daffodils, but when it was discovered the top soil was removed and the mould did not reappear. Sterilising the bones as well as the soil would reduce their manurial properties. We should advise you to keep a careful watch on the soil in the pots, but the mould may not be due to the bones so much as to the place in which you have kept the unused compost, as it sometimes arises in a close atmosphere. Another cause which we have found was by mixing the soil when it was too wet. We find basic slag safer than bone-meal for Daffodils, seeing that there are so many inferior kinds of the latter soil.

PLAN OF HERBACEOUS BORDER (Cestrian).—Your plan is well conceived, and should give you a continuous display for the period you mention, although, of course, some of the plants will not remain in flower the whole period. You do not say what Coreopsis you intend using, but if the Monarda is properly grown it should overtop the former, and would, therefore, be better behind instead of in front of the Coreopsis. C. grandiflora is the best, but is not long-lived. But for the fact that you require to lighten up the part occupied by the Rhododendrons in autumn, both the Monarda and Anemone japonica would be better on the side with slight shade. As things are, they will be better where you have put them, but they should be liberally treated. We presume you will use a white variety of A. japonica. If you mean to use both Heuchera Walker's variety and H. Rosamund, the latter is the taller of the two. If you mean Helianthemum pumilum grandiflorum or magnificum by the initials "P. G.," you will find it rather taller than the perennial Gaillardia if properly grown. With the slight alterations indicated, we think your border should give a good effect, although much will depend upon the seasons.

TREES AND SHRUBS.

CLIMBERS FOR COVERING THE SOUTH AND EAST WALLS OF A MANSION QUICKLY (Hamish).—The following plants will be likely to suit your purpose: Wistaria chinensis, W. multipecta, Clematis montana, C. m. rubens, Aristolochia Sipho, Hydrangea petiolaris, Tecoma grandiflora, Vitis henryana, V. Coignetie, Jasminum officinale, J. nudiflorum, and, though not climbers, Crataegus Pyracantha and Magnolia grandiflora. If you do not mind very common plants, the quickest-growing of all climbers is Ampelopsis Veitchii, while the large-leaved Ivies also make rapid growth.

CLIMBERS FOR A WALL (K. Manwaring).—The following climbers, &c., are likely to give satisfactory results against your walls: For the south wall, where you wish to have Roses, use William A. Richardson, Gloire de Dijon, Climbing Mrs. W. J. Grant, Climbing Souvenir de la Malmaison, Ards Rover, Belle Lyonnaise, Bonquet d'Or, Cheshunt Hybrid, Ards Pillar, Amée Vibert and Ards Rambler. Against the west wall you might plant Wistaria chinensis, Ceanothus rigidus, Magnolia grandiflora and Clematis montana. On the south-east wall Wistaria multipecta, Jasminum nudiflorum, J. officinale and Clematis montana rubens would do well; while the north wall might be covered with Crataegus Pyracantha, Ampelopsis Veitchii, and Clematis Jackmanii and varieties. Against the terrace wall the following plants would thrive: Ceanothus Veitchianus, Escallonia macrantha, E. langleyensis, Chimnanthus fragrans grandiflora, Garrya elliptica (male form), Hydrangea petiolaris, Corokia Cotoneaster, Myrtus communis, Prunus triloba flore pleno and Cydonia japonica var. cardinalis.

TRANSPLANTING A MONKEY PUZZLE (B. A. M.).—Had you stated the size of the tree you wish to move, it would be easier to answer the question. The second half of September is a very good time to move such trees. A tree 4 feet or 6 feet in height may be safely transplanted by carefully digging it out with a fork, saving all the fibrous roots possible. Lift the roots on to a mat or large sack, on which to carry the tree to the new position. Water the tree after planting, if necessary. Larger trees are more safely transplanted with a large ball of soil. A trench is first of all dug round the tree at a convenient distance to expose the ball of soil, 2 feet or more in diameter, according to the size of the tree. Next bind a canvas sheet or mats round the ball of soil with soft cord. At a convenient depth, from 15 inches to 18 inches, work the soil from under the ball on either side to permit two boards to be placed in position to lift the tree. When too large to lift out of the hole by men, a transplanting machine may be used, or a sloping trench made down to the hole, up which the ball of soil may be dragged on rollers and planks. After removal, syringe the plant for a month on every evening following a dry, sunny day.

EDITORIAL NOTICES.

Every department of horticulture is represented in **THE GARDEN**, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in **THE GARDEN** will alone be recognised as acceptance.

Office: 20, Tavistock Street, Covent Garden, W.C.

NOTES OF THE WEEK.

Our Special Rose Number.—On October 11 we shall publish a specially-enlarged number, which will contain many interesting and practical articles on the raising and cultivation of Roses. The numerous illustrations will be of a unique character, and as the date coincides with the commencement of the planting season, there is certain to be a great demand for that issue. We advise readers who require extra copies to order them in advance.

Japanese Grasshoppers.—At a recent meeting of the scientific committee of the Royal Horticultural Society, Mr. Goodacre of Moulton Paddocks sent a number of Japanese grasshoppers (*Diastemma marmorata*), and observed that the insects had established themselves in the large conservatory at Moulton, and had also invaded the mansion. The problem now was to exterminate them. They are large, handsome insects in the larvæ stage. When fully matured they will be very formidable-looking creatures.

A Beautiful Plantain Lily.—In *Funkia tardiflora*, as the name suggests, we have a most attractive late-flowering Plantain Lily, at its best towards the end of September or early in October. Choose a sheltered spot to plant the roots, as an early frost in October would spoil the flowers in an exposed position. As an edging to a half-shady border or a sheltered nook in the rockery, *Funkia tardiflora* is especially effective. The spikes of lilac-tinted flowers reach about a foot in height.

Maw's Heath.—Flowering from August to October, *Erica mawiana* is one of our most valuable and attractive autumn-flowering Heaths. Growing 1 foot to 18 inches high, the small bushes are freely clothed with clusters of purplish red flowers. Its origin is uncertain; though given in the "Kew Hand List of Trees and Shrubs" as a variety of *E. ciliaris*, it is probably a hybrid between that species and some other Heath. In addition to its value for planting in the pleasure grounds and shrubbery borders, Maw's Heath is worth a place in the rock garden.

Shirley Poppies and Cornflowers.—During last summer, when on a visit to the gardens of Mr. H. F. Nicholl, Bear Place, Twyford, we saw a pretty bed of Shirley Poppies intermixed with Cornflowers. It was a chance shot, as they say, but it will be repeated again. The Shirley Poppies are showy plants, and for hardiness and easy cultivation cannot be excelled; while among the Cornflowers will be found various shades of blue, a colour lacking in the Poppies. It is one of the loveliest of our blue-flowered annuals, and is extremely useful for cutting and decorative purposes. Seeds of the above may be sown both in the autumn and spring, the former time being chosen for early blooming and the latter for a succession or later supply.

The Japanese Anemone.—The rosy carmine *Anemone japonica* is well known at this season of the year by the fine display it makes in the border or bed. There is also a white variety known as *alba*, which produces its chaste blossoms freely from August to November; but the best white in commerce is undoubtedly that which goes under the name of *Géante des Blanches*. The silvery white flowers are large and about three inches or four inches in diameter, while the plants grow from 18 inches to 30 inches high. These Anemones are among the handsomest of border plants. They will thrive in almost any garden or position, and may be readily increased by division.

Varieties of the Common Ling.—There are numerous forms or varieties of *Calluna* or *Erica vulgaris* deserving of liberal planting in the pleasure grounds and woodland. In gardens where there is little or no lime in the soil we ought to make much greater use of these and other autumn-flowering Heaths, as they blossom at a time when there are few trees and shrubs in flower in the pleasure grounds and shrubbery borders. Half-a-dozen of the most distinct varieties are *Alportia*, a strong-growing, crimson-flowered form; *Serlei*, stiff, upright growth, white; *rubra*, rosy red; *flore pleno*, double rose; *alba*, the popular white Heather; and *rosea*, rose.

A Free-Flowering Pentstemon.—Though of comparatively recent introduction, *Pentstemon Southgate Gem* is rapidly increasing in popular favour. A hybrid between *Hartwegii* (*Newbury Gem*) and one of the large-flowered sorts, *Southgate Gem* inherits the free-flowering qualities of *Hartwegii*, and has considerably larger bright red flowers. For the past two months four large beds (containing about two hundred and fifty plants in each) in front of the Palm House at Kew have been admired by thousands of visitors, and a succession of flowers seems assured for some time to come, judging by the number of unopened buds.

Stopping Mealy Bug on Grapes.—Every gardener who has attempted to grow Grapes is fully aware of the loathsome character of the mealy bug, an insect that ensconces itself between the berries and renders the fruit almost useless. No matter what precautions are taken to eradicate this pest from the house, a few insects are almost certain to escape. Last week, when visiting some well-known nurseries in the Midlands, we were interested to see that the sticky substance, such as tanglefoot, used for grease-banding fruit trees, had been used on the Vines. A very small quantity had been smeared around each Vine shoot just where a bunch had emanated, and this, the owner assured us, had effectively prevented the insects reaching the fruit. Certainly we failed to detect their presence in any of the bunches the stems of which had been so treated, and we record the method for the benefit of those who care to give it a trial another year. The sticky substance should be put on almost as soon as the bunches are formed.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Scentless Musk.—The old-fashioned small Musk in this garden, and at Sudbrooke Holme, near here, has quite lost its smell. I have had my stock twenty-six years.—(Mrs.) E. SANDARS, *Scampton House, near Lincoln.*

Polyantha Rose Leonie Lamesch.—I have just seen this lovely Polyantha for the first time, and I am so enamoured of it that I cannot refrain from bringing it to the notice of the readers of THE GARDEN, so that any of them who may contemplate planting may consider its claims to a place in their collection. It is rightly described as "a deep coppery red, shaded with yellow; an exceedingly attractive colour." I find that it was introduced so far back as 1809.—CALLEDONIA.

Rose Augustine Guinoisseau.—I planted a dwarf of this Rose about six years ago. Hitherto it has borne normal blooms, white, tinted blush. This year there is one bloom on it similar to La France in colour and shape. If the Rose was originally a sport of La France, as its alternative name White La France would imply, this is an interesting case of reversion after several years of cutting back. I should be glad to learn whether any of your readers have noticed the same thing in this or any other sport.—R. F. COBBOLD, *Beachampton Rectory, Stony Stratford.*

Tropæolum canariense.—When well cultivated this plant has few rivals in the matter of furnishing a screen, wall, or trellis with beautiful foliage and lovely flowers. While passing a villa residence recently I saw a very fine specimen, the largest and best I have noticed in any garden, quite hiding a portion of trellis and wall measuring about nine feet by five feet. There were hundreds—I may say thousands—of yellow blossoms on the plant, which was shown to great advantage by the luxuriant and bronzing leaves of an Ampelopsis near them. The aspect is north-west, and only gets sunshine late in the afternoon. Splendid plants may be raised by sowing seeds in a frame the first week in April.—AVON.

The Orleans Rose in Scotland.—One of the best and most useful of the many good Roses in the admirably-selected collection in the garden of Mr. C. E. Galbraith at Terregles, Dumfries, is the Orleans Rose, a fine bed of which has been doing very well this season, and which was a mass of bloom in the beginning of September. Raised by Levassieur and sent out in 1809, it has rapidly acquired great favour, and at Terregles it is highly appreciated. Of vigorous growth, it gives an abundance of its great trusses of flowers, which have been well described as rosy red with a peach centre. Roses are well grown at Terregles by Mr. W. Hutchinson, the gardener, who thinks highly of this fine Polyantha variety.—S. A.

The Late Blooming of Wichuriana Roses.—During last winter I had occasion to plant a long row—some 400 yards—of standard wichurianas. The plants were not large-headed, and were pruned back about half way. They came into flower a fortnight later than the general run of established plants upon the same ground, and early in September were very fine. A lot of new growths broke after the trying spring, and these flowered freely. Among the best plants are Excelsa, Debutante, Christian Curle, Delight, Hawatha, Minnehaha, Dorothy Denison and the white single type, wichuriana alba. I have never

noticed them so full of flower so late, and wonder if others have experienced the same. My plants promise to last through the best part of the present month. American Pillar is also grand under similar conditions now, and has been for a long time.—A. P.

Primula littoniana Hardy in Scotland.—It will perhaps be interesting to many readers of THE GARDEN to know that this beautiful species, from the mountains of Western China, has proved perfectly hardy here. In the rockery I have a plant in perfect health and carrying four fine spikes. It passed through last winter's frost unprotected, and our severest frost was 21°. I should also like to mention that *P. cockburniana* and *P. bulleyana* have proved quite hardy here without any protection whatever, have flowered exceedingly well, and show every prospect of ripening a good crop of seed. *P. cockburniana* is quite perennial with us. I am planting a good many *Primula Forresterii* and *P. Veitchii* for next winter's test. We plant large, bold masses of each species, and thus obtain a charming effect.—WILLIAM HUNT, *Saughton House, Middlethun.*

Annual Larkspurs and Aster diffusus.—May I draw the attention of your readers to an easily-grown, cheap and effective combination either for a single bed or for a group in an ordinary border? I refer to the annual Larkspur and the small-leaved *Aster diffusus*. Plant single pieces, not clumps, of the *Aster* in April from 2 feet to 3 feet apart and grow to a single stem. Sow the Larkspur between them and thin out or transplant, so that the two plants are evenly distributed. The foliage of the *Asters* supports and clothes the bare, straggling branches of the annual, and forms an excellent setting to the flowers. By removing the seed-pods the Larkspurs will keep on flowering till September, when they may be pulled up, the bed of *Aster diffusus* remaining for the rest of the autumn. If the *Asters* show a tendency to grow too strong, they will stand any amount of thinning. A poor soil is best.—SURREY.

Salvia involucrata Bethellii.—May I ask if any readers of THE GARDEN are acquainted with *Salvia involucrata* variety *Bethellii*? It has proved a great success with me as a plant for the open border, though I am told it is not quite hardy. I had it in a cold house all last winter and planted it out in May, when it began to grow quickly and showed flower-buds in July, since which it has gone on developing spike after spike of brilliant rose pink flowers, the bush being now $3\frac{1}{2}$ feet high and as much across. The leaves are a beautiful shining green and the stems reddish, the whole forming an extremely handsome plant. The side-shoots are now preparing to bloom, so that if mild weather continues it will be even more showy in a few weeks' time than it is now. It seems to me a plant well worth growing, even if I cannot keep it out of doors through the winter, but I do not feel at all certain that this is the case.—SILINA RANDOLPH, *Chartham, Canterbury.*

Growing Liliium giganteum.—There is no doubt that a partially-shaded spot is best for this noble Lily, while a sandy border in a town garden referred to on page 419 is as undesirable a place as well could be. In any attempt to grow it in poor, sandy soil, a large hole should be taken out and filled with some good compost, in which, however, crude manure plays no part. Another important feature is that, though large bulbs are often offered during the winter months, they rarely, if ever, give satisfaction, as they already contain the flowers in embryo, and have not time to become established

before the stem is pushed up. The blossoms are therefore mainly dependent for their development upon the substance of the bulb, and consequently the stem is puny and the flowers the same. The bulbs should be planted when small, so that there is ample time for them to become established before the strain of flowering comes round.—H. P.

About Two Old Roses.—We have two beautiful old varieties growing on a fence that are scarcely ever referred to, namely, *Rose Ophirie* and the *Yellow Banksian Rose*. But what a vast difference in their behaviour we experience! Both grow splendidly, and there the latter stops, while *Ophirie* never fails to flower. It was, the first week in August, covered with some very fine flowers, which are of a salmon and coppery hue. As the flowers expand they have a flattish appearance, not unlike those of *Gloire de Dijon*. The colour of *Rose Ophirie* makes a very pleasing contrast from the many shades of reds and pinks of the rambler section. Our plant is growing on a south-west fence. Growing next to it, some of their growths being interlaced, is the *Yellow Banksian Rose*, and I can honestly write it has not yielded one handful of flowers during the last ten years—the time it has been planted. It is a most healthy plant, with fine, clean growths and glossy foliage. The latter is one of its good features, and being thornless is another; but all leaves and no flowers for ten years is a bit too "barefaced." And so it is quite possible that the year 1913 will ring its death knell.—C. T., *Ken View Garden, Highgate.*

Protecting Rambler Roses.—"Amateur" on page 442 mentions the tenderness of ramblers during winter. The idea of lifting as a means of checking the late sap so prevalent with this class of vigorous grower is good, and I have found some live a little better through it. But one cannot lift old, well-wooded specimens, nor will the bulk of last season's growth be of much service for future blooming, unless it can be brought through the winter and still remain upon more or less established roots. "Amateur" does not state where he lives, but I can confirm the havoc done by the severe early frosts in the North; and upon more than one occasion ramblers have suffered sadly in the colder districts, especially if accompanied by keen winds. A slight lifting or root pruning with the spade as the plants stand would probably check sap a little; but if the ground is warm, new roots would at once spring out and afford an even later supply until frost came. Much might be done towards securing better and more finished growth if the shoots were kept thinned to allow of ample light and air among the wood. In a bleak and exposed position any Rose will suffer from sharp frost, and the fact of our ramblers growing so late during the moister days of autumn makes them far more liable to attack than Roses which naturally mature earlier. A little protection in the way of large, feathered branches of Hazel, Spruce or Gorse, placed at a little distance and upon the weather side of the plants, has been tried, with excellent results; but I do not quite like the idea of wrapping the growths in Braeken or straw. Some of our ramblers and some of the newer Hybrid Wichurianas are more tender than others. I have found American Pillar, François Crousse, *Gloire de Dijon*, *Helène*, Longworth Rambler, *Mme. Alfred Carrière*, *Polyantha grandiflora*, *Rève d'Or*, *Trier*, *Félicité Perpétue*, *Dawn*, and the weeping form of *Rosa rugosa* (*R. r. repens alba*) about the hardiest of all pillar or rambling Roses.—A. P.

A Beautiful Dark Rose.—I should like to call attention to Rose Château de Clos Vougeot. It is one of the best, if not the best, black maroon Roses which we have for bedding. Its colour may be best described as blackish maroon shaded with fiery red and velvety crimson. So far as I have been able to judge, it is better on the Briar stock than on the Manetti. On good land the growth is fairly vigorous, but it is advisable for bedding purposes to plant rather thickly, 18 inches apart being a suitable distance from plant to plant. It is a good autumn Rose, good flowers being produced at the date of writing (September 19). So far our plants are quite free from mildew, although other varieties of Roses near by are affected.—*CORIN ROSE, Sulhamstead.*

Iris Kämpferi in Japan.—The accompanying illustration shows a portion of the Iris grounds of the Yokohama Nursery Company in Japan. This delightful spot is situated a few miles from the head nursery in Yokohama, and is reached by tram and train. When the flowers are at their best, the gardens are extensively advertised throughout Japan, and thousands of visitors go there annually. It is undoubtedly the largest Iris Kämpferi nursery in the world, covering many acres in extent. The exports of this popular plant are made in mid-winter, when the clumps are quite dormant. They are usually packed in small cases, and travel most successfully to all parts of the world. Judging from the large, well-flowered groups of this plant exhibited at recent exhibitions in England, its cultivation has evidently much improved in this country.

Antirrhinum rupestre in an Irish Garden.—This plant differs so much from the erect-growing kinds that a few remarks as to its qualities and habit of growth may not be out of place. As a rock plant it has few rivals. Its sulphur and yellow flowers contrast well with the scarlet Lotus peliorhynchus. Both plants are of a trailing habit, and will creep over rocks in a most wonderful fashion. *A. rupestre* should be planted in sandy soil, always choosing a sheltered position. It is quite hardy here, and will live out of doors all the year round and continue in bloom until late in the autumn. It may be also seen here in company with that beautiful scarlet *Tropaeolum speciosum*, which annually makes its way through a closely-clipped Privet hedge fully 4 feet in height, on the top of which it wanders carelessly, bearing its racemes of brilliant scarlet flowers and forming a picture of beauty more easily imagined than described. Peeping here and there through the Privet hedge may be seen healthy sprays of *A. rupestre*, which has travelled from the bottom the flowers and foliage of which differ so much from the other subjects as to give a most pleasing effect. *A. rupestre* may be propagated by cuttings in the autumn or by seed sown in gentle heat in early spring. I consider the latter method of propagation the best, as the plants come stronger and furnish better.—*S. BRYAN, Fortfala House, Leenore, County Dublin.*

Campanula cenisia alba. This really very lovely plant is now in full flower for the second time this summer. I owe it to the kindness of a fellow-enthusiast, Mr. Tucker of Oxford; but the remoter history of the form I do not know, though I remember that an albino was once discovered by Mme. Corroyon. Often though I have found the species myself, I do not think I have ever seen anything more marked in the way of variation than a delicate silver-pale form; certainly no albino. And wonderful as is the subtle grey-blue charm of *C. cenisia*, type, huddled in dense masses of blossom tight among the dark stones of the highest meadows, it must undoubtedly yield to the beauty of this albino, which is as generous of blossom as its original, but with large flowers of the richest creamy whiteness, most fascinating to behold. It is growing robustly in a mixture of

THE CAMPANULAS.

WITH reference to the excellent series of papers on Campanula now running through THE GARDEN, may I point out that *C. alpestris*, All. 1755, is the prior, and therefore the *only* proper name for *C. Allionii*, Vill. 1779. Let all gardeners and catalogues promptly take note. No obscurity is involved; the point is absolutely plain and certain. The oldest name, like truth, must in all cases ultimately prevail, although, like truth's, the battle may often be doubtful and long. Well do I know the bitterness of thus having to change names and revise conceptions, yet nowadays it is of the most vital importance, alike to buyers and sellers, that we should all make

AN IRIS NURSERY IN JAPAN.

peat, leaf-mould and very rough sand in a bed where water is perpetually percolating from a pierced pipe some 12 inches below the surface. This will, of course, be turned off in the winter, and in the meantime this rather difficult and exacting species so wholly appreciates its treatment that not only is it thriving heartily itself, but has also deposited already at least three prosperous seedlings—a freedom of which I have never yet known *C. cenisia* to be guilty of in the garden before. And such care, so rewarded, is well deserved by a species so delicately lovely as *C. cenisia* with its albino.—*REGINALD FARRER*

FORTHCOMING EVENTS.

October 1.—National Chrysanthemum Society's Show at the Crystal Palace (two days). County Clare Horticultural Society's Fruit and Farm Produce Show

a great effort to secure uniformity and accuracy in our nomenclature, for even bitterer than learning a right name instead of a wrong is the bitterness of buying some expensive novelty under half-a-dozen different names, and then, at the end, discovering that it is really some quite ordinary plant that you had all along possessed under another.

Yet more conspicuous, however, is the fearful confusion that now rages in gardening books as well as in THE GARDEN, in all catalogues and all gardens alike, over *C. pusilla* and *C. caespitosa*. To this confusion I myself have also added no longer ago than last year. Let me now make amends by an attempt to unveil truth. First of all, the plant universally prevailing in our gardens under various names and in varying forms is everywhere and always *C. pusilla*, Haenke (*C. modesta* and *C. pumila* are *nomina nuda*),

THE PINK BUGLE LILY OR WATSONIA ROSEA.

To *C. pusilla* belong all the named forms, such as *C. p. Miss Willmott* and the very glorious *C. p. Miranda*, on which a note has already appeared prematurely in *THE GARDEN*—prematurely in that *C. Miranda* dare not face popular enthusiasm for some time yet to come. No description is necessary of *C. pusilla*; no garden is without it. On the other hand, *C. caespitosa*, Scop., is a perfectly distinct and sound species, almost, if not wholly, unknown in cultivation, although of the most remarkable beauty and the most easy-going constitution. It may be recognised at once by its characteristics—one dense caespitose tuft from a single tap-root, *never* ramifying after the fashion of *C. pusilla*; the barren shoots very densely packed with stiff, lanceolate, shining little leaves, which are also crowded at the base of the flower-stems (I see no diagnostic of difference between the two species in the form of leaf itself). These are much taller and slenderer than in *C. pusilla*, attaining often to 15 inches to 18 inches, whereas *C. pusilla* seldom, if ever, exceeds 6 inches. The flowers are more numerous along the upper part of the stem, delicately pendulous at intervals. They are of a rich soft blue, longitudinally ribbed in a marked and most attractive way, and slightly constricted towards the mouth so as to have the effect of a little swinging Japanese lantern. This most delightful of Campanulids belongs to the Eastern ranges. The most westerly record of my own is in the Ampezzothal between Toblach and Cortina, where it occurs rather sparsely and out of character; whereas in the Karawanken it comes to its full delicacy of glory, waving blue carillons over all the roadside banks and gravelly cuttings with the wiry, airy grace of *Dierama pulcherrimum*

(Is it possible the Royal Horticultural Society's Journal should allow this to be spoken of as *Dierama pulcherrima*? Oh! that fatally feminine-looking Greek neuter termination in "ma"; yet *Ethiomena* gets its right gender nowadays.) *C. caespitosa* is a more lowland plant than *C. pusilla*, which seemed to me curiously rare and alpine in the Karawanken. I only happened on it once high up, when the botanist who accompanied me called it *C. Scheuchzeri*—a fact which sheds a lurid light on the confusions that arise in gardens among plants purchased from "collectors." *C. caespitosa* never, I think, ascends to the usual altitudes of *C. pusilla*, but in its own ranges replaces *C. pusilla* in sandy, gravelly places, banks, roadsides, field margins and cuttings. These conditions, or, indeed, any others, suit it admirably in cultivation, where it is not a whit less hearty and satisfactory than *C. pusilla*, setting up, too, to claim our affection with a beauty wholly distinct from that of its rival, a beauty sparkling and gracious and full of an airy charm beyond the reach or aim of the lower-growing, stumper and more invasive little harebells of *C. pusilla*. REGINALD PARKER.

THE FLOWER GARDEN.

THE BUGLE LILIES, OR WATSONIAS.

THE Bugle Lilies, or Watsonias, are attractive and interesting plants, hailing from South Africa. There are only two species which are at present popular in gardens, viz., *Watsonia alba*, otherwise known as *W. Ardernei*, and *W. rosea*, and as they are now procurable at a cheap rate and of easy culture, there is no possible reason why they should not become more popular still, as they are admirably adapted for general garden decoration as well as for pot culture. For growing in the border, successional plantings during spring will result in a flowering period extending from July to October. When planted on heavy soil, it is perhaps advisable to lift after flowering, drying well, and storing as in the case of choice Gladioli, replanting them the following spring; but in certain cases on light soils they can remain out during the winter if a light covering of Bracken or other light material is provided.

Watsonia rosea, the subject of the illustration, is a time-honoured favourite in our gardens, having been introduced from South Africa so long ago as 1807. It has recently been shown in quantity, of surpassing beauty, by Mr. James Box of Hayward's Heath. By some botanical authorities it has been described and figured under the name of *Gladiolus pyramidatus*. Although not so often seen in gardens as *Watsonia alba*, it is, nevertheless, a pretty species, growing over four feet in height, with bright rose flowers, freely disposed, on long branching spikes, and long, broad green leaves. Other species of this family occasionally met with, such as *Watsonia angusta* (with small scarlet flowers), *W. cocinea* (flowers bright crimson), and *W. densiflora*, are among the best of this small family of bulbous plants.

A BRAZILIAN SALVIA.

(*S. ULIGINOSA*.)

CONSIDERABLE interest is being displayed in this *Salvia*, which hails from Brazil and is described in last week's issue (page 476) under the heading of "New and Rare Plants." This species has recently received an award of merit from the Royal

Horticultural Society. In many ways it is less attractive than other species well known to cultivation, but Mr. Turner of Slough, who exhibited the plant on the occasion referred to, describes it as a hardy herbaceous perennial. It is unquestionably a near ally of *Salvia azurea* and *S. Pitehieri*, both well-known greenhouse plants; but there is reason to hope that the new-comer will prove hardier than either of these. *S. uliginosa* is a vigorous grower, reaching 4 feet to 6 feet in height, and the flowers, produced in dense terminating spikes, supply a clear shade of azure blue that is almost certain to be greatly prized in the gardens of this country.

THE ROSE GARDEN.

GOLD MEDAL ROSES AT THE AUTUMN SHOW.

THERE was much speculation as to what Ireland would send in the matter of new Roses, for it is well known that the three eminent raisers in the Emerald Isle have a wealth of novelties of a quality never yet attained before. However, the weather has been against them, as it has been for us in England, and this was reflected in the novelties staged, some of which were, no doubt, excellent, but scarcely up to the standard necessary for a gold medal. The awarding of

HYBRID SAXIFRAGES.

THE great rise in popularity of rock gardening has been accompanied by a corresponding improvement among those flowers which are essential to the alpine garden. At no time have the Mossy Saxifrages been in greater favour than they are to-day. Among those to whom we are indebted for improved varieties should be mentioned Mrs. Lloyd Edwards, whose exhibits of these charming flowers, notably at

some characteristics of each, but it was a great improvement on both in every way. This I named Apple Blossom, and it gave me the idea of trying to produce some large-flowered, bright-coloured varieties by hybridising. I had already had great success in trying to get a free-flowering race of Heucheras by this means. I used the new seedling S. Apple Blossom, S. Rhei superba and S. Guildford Seedling, and soon got some very beautiful large-flowered Mossies of different shades of colour and vigorous growth. About this time Messrs. Thompson and Morgan of Ipswich advertised among their seed novelties S. decipiens hybrida grandiflora. I bought a packet and crossed some of the resulting seedlings with my own,

to their mutual improvement. A fine red seedling I named Ruby. This flowered twice in its first season, and was purchased by Messrs. Chibran's representative for a small sum. He saw it in flower in the autumn and was much struck by it. As S. Chibran it has gained a considerable reputation. I continued selecting and cross-fertilising my best seedlings and produced Red Admiral, an improvement on Chibran in size and colour. I wanted a really blood red Saxifrage, free-flowering and of compact growth, and in time got S. sanguinea superba. It shows in its neat, neatly-cut foliage that S. Guildford Seedling was among its ancestors, and, as far as colouring is concerned, I think no redder Saxifrage can be produced. In the process of obtaining it I got many beautiful rose coloured and shaded Saxifrages, notably S. rosea superba, a very fine, free-flowering early variety with dark stems and red buds; and S. Rose Beauty, with beautifully-shaped flowers with small centres, which flowers very late. There was an idea that S. decipiens hybrida grandiflora of Messrs. Thompson and Morgan had been partly produced from S. granulata; but none that I raised showed any trace of such parentage. I, however, experimented in this direction and effected a cross between one of my finest red Mossies and a wild S. granulata, and from this raised Comet, White Queen, &c. These show their derivation very plainly in their partly granulated roots, leaty tufted growth, and in partially or wholly losing their leaves for a

longer or shorter time. Nearly all the seedlings were white; some had pink buds; but, so far, I have not raised a red granulata hybrid. All are extraordinarily floriferous. The second generation of this cross produced some very beautiful large Mossy Saxifrages, such as Mrs. J. I. Tottenham and S. oculata rosea, which, with S. sanguinea superba, S. Rose Beauty and S. Comet, is shown in the coloured plate.

"I referred above to my first attempt at improving plants by hybridisation. That well-known amateur gardener, the late Rev. C. Wolley-Dod, gave me a dingy pink hybrid Heuchera from which I succeeded in getting many charming varieties by crossing it with H. sanguinea."

gold medals is becoming quite a fad. When one of these coveted medals is awarded, as it was on this occasion, to a Rose like

Moonlight (the Rev. J. H. Pemberton), it seems the height of absurdity. If the award had gone to Danæ, I should not have been surprised, because this Rose is a great advance in colour in this new section of Hybrid Multifloras; but to give it to Moonlight, which can only claim being "pretty," is an error of judgment. I believe the award was only given by a bare majority. Now in

Muriel Dickson (Hugh Dickson, Limited) we have one of the most striking novelties. Perhaps the casual onlooker would not see anything great about it; but the writer, who has seen it in Ireland, can give it unqualified praise. The colour is a wonderful shade of cerise, with quite an orange glow about it. This latter colour comes from its relationship to the wonderful Pernetiana group, a relationship that is manifest in its growth as well as in its bloom. The flower is of a fine bold type that will ensure it a great popularity.

Edward Bohane (Alex. Dickson and Sons) is also a "great" Rose, of the wonderful colour of a very good George C. Wand, with a more massive petal. This variety was illustrated in THE GARDEN of October 12, 1912, page 514. The growth is splendid and the foliage superb. I have seen this at Newtownards, and have no hesitation in saying it is worthy to be termed a genuine "Hawthorn" variety.

Edgar M. Burnett (S. McGredy and Son) is a giant among bluish pink Roses, and will be a most useful variety for the show-box and for the garden. See illustration. Its colour seems to come midway between La Tosca and Lady Mary Fitzwilliam, and it has immense petals, perfectly arranged. From the plant exhibited it is evidently a fine garden Rose also.

Red Letter Day (Alex. Dickson and Sons) obtained the coveted gold medal, and, I think, quite worthily, for although only a semi-double flower, it is of such a glorious rich blackish crimson colour and so profuse in its blooming that it will be a really splendid addition to garden Roses and a formidable rival to Irish Fireflame and Irish Elegance. Red Letter Day is a splendid grower, one that can be used for a 5-foot or 6-foot hedge, or even more, and is constantly in bloom. When I saw it in its home at Newtownards recently it caught the eye immediately, and I was much impressed by its gorgeous colour and effect on the plants. It is gratifying to know that all three of the Irish raisers are paying attention to these garden Roses as well as to those of the exhibition type, and I especially welcome such sorts as Muriel Dickson and Edward Bohane, which may be used for both purposes, for this is what we want nowadays—Roses that are splendid in the garden, yielding blooms of quality in rich profusion.

THE NEW ROSE EDGAR M. BURNETT. AWARDED THE NATIONAL ROSE SOCIETY'S GOLD MEDAL.

the Royal Horticultural Society's meetings, have aroused much interest from an admiring public. In the matter of the hybridisation of the Mossy Saxifrages, Mrs. Lloyd Edwards' experience is here related in her own words:

"A few years ago the only Mossy Saxifrages with coloured flowers of any size were S. Rhei superba and S. Guildford Seedling, the former with pale rose flowers of good form, and the latter with rather small, bright red flowers, not very free-flowering or particularly vigorous in growth. One spring a self-sown seedling Mossy Saxifrage appeared in my little rock garden. It was probably a cross between S. Rhei superba and a cream-coloured, hairy variety called, I think, S. hirta, as it had

DANECROFT.

ROCK AND WATER GARDEN.

MICHAUXIA TCHIHATCHEFFII.

THIS stately plant, belonging to the Order Campanulaceae, is a native of Asia Minor, and in our gardens grows best in a very sunny, well-drained border or against a south wall, its large, fleshy and brittle roots requiring a thorough rest and no standing water from September to April. The growing season of this plant is surprisingly short, as directly after ripening its seed in August the stems and leaves die completely down. The root "throws up" again in March and April, and it will attain great age when planted in a suitable position. Unless it is absolutely necessary, a plant once suited should on no account be shifted, as it intensely dislikes removal. The most satisfactory way of propagating is by seed, which germinates readily, but takes four years to reach the flowering stage. This *Michauxia* produces branching spikes 3 feet to 4 feet high, covered in June and July with very pale blue, almost white, flowers, somewhat resembling Passion Flowers, the petals of which are turned back, while the stigma is very large and conspicuous. The foliage is of a glaucous colour and very hirsute. The flowers of *Michauxia Tchihatcheffii* never vary much in colour, though another species, *M. campanuloides*, of easier culture, has rose to white flowers.

REGINALD A. MALBY.

THE FRUIT GARDEN.

THE BLACKBERRY AS A GARDEN FRUIT.

AS this is the season of the Blackberry, perhaps a word in its favour as showing its usefulness and value under cultivation, in contradistinction to its value as a hedgerow fruit, may be useful to town as well as to country readers of *THE GARDEN*. Four years ago I had a few young plants sent me of a variety which was said to be *par excellence* a good sort. I had been for some time looking out for a useful climbing plant for the purpose of making a screen from one portion of the garden, and also to afford some shade to the kitchen window from the midday sun. I concluded that these would be useful for the purpose, and planted two of them, erecting a rough trellis of poles for the plants to ramble over. One of the plants took the lead over the other, and is now practically responsible for the fruit since gathered, and also for forming an effective screen.

The result is that the year before last we gathered 7 lb. of fruit; last year we gathered 10 lb.; and this year, up to date (September 8), we have gathered 24 lb., with a promise of from 6 lb. to 10 lb. more to come. The fruit is large—half as large again as the hedgerow Blackberry—an intense black colour, and sweet. It has proved most useful. Mixed with Apples, it is excellent for tarts and puddings, and for jelly, either alone or mixed with Apples. The plant I am speaking of is growing in a London suburban garden under the same conditions as

many thousands of houses similarly situated in London and other towns. To those who care for the Blackberry and who may have places such as I have described which they wish to have screened, I very strongly recommend them to plant the humble Blackberry. One of the best sorts to plant is the variety named Parsley-leaved.

A word as to the culture adopted. This is simple, and entails but little trouble and practically no cost. The corner of the garden in which the plant was planted was trenched and liberally manured four years ago. During the summer months the border is mulched with rotten stable

A STATELY PLANT OF THE CAMPANULA FAMILY, MICHAUXIA TCHIHATCHEFFII.

manure, and, during the whole time the fruit is swelling, the border receives heavy occasional waterings, averaging about once a fortnight. The border is 5 feet by 5 feet.

The shoots the plant is making this year are most vigorous, many of them being 20 feet long. These will produce the best fruit next year. These shoots are permitted to grow freely, as they will, until all the fruit has been gathered. Then the branches which have borne fruit are overhauled, and all the weakest of them cut out down to their base to make room for the young branches spoken of above.

HOW TO GATHER AND STORE HARDY FRUITS.

Apples and Pears must receive first attention, as they are the most important of our hardy fruits for long storage. Medlars, Quinces and Nuts also deserve great care in the matter of storing. There is no need to pay particular attention to the storing of the earliest Apples and Pears, as these are quickly used up; but the varieties that are wanted for use throughout the winter and spring should have, and deserve, great care bestowed on them, as there are few other kinds of fruits to take their place.

Gathering and Grading.—Many cultivators in this country entirely neglect to pay special attention to the gathering and grading of the fruits, and consequently, through this carelessness, much loss results. Wherever possible, steps should be used instead of ladders, as the latter must be supported by the branches, and when the weight of the person gathering is added to it, the pressure often causes much bruising of fruits. Steps stand clear of the branches, and, when firmly fixed, are safer than ladders, which are supported, in many instances, by slender branches only. Very often the gatherer places the fruits in an apron pocket, an apron tied up, or in a bag. The fruits roll to and fro with every movement of the workman, and so the first bruises are made. They are also placed in baskets, trugs or boxes without any soft lining of moss or wood-wool being put in, and frequently rolled out of all such receptacles on to a bench or shelf, and the second lot of bruises are made. Fruits so treated will not keep in a sound condition throughout the winter months. The proper way to gather Apples and Pears is to grasp each specimen firmly with the fingers, raise it to a horizontal position, when, if ripe enough, it will readily part from the branch, and place it gently on a layer of soft material in a flat basket or box. Several baskets should be in use at the same time, and, when filled as suggested, carried to the store-room, and the fruits removed to the shelves separately. If the grading cannot be conveniently done when the fruit is being gathered, it can when it is placed on the shelves. Give the finest fruits the best positions in the store-room, the seconds in the next best position, and the small ones in heaps or on shelves by themselves, as they should be used first. Apples do best in the coolest part of a room. Shelves made of clean, unpainted battens are the best. Do not use straw on which to place the fruits, and put them down in single layers.

Ventilation is a very important matter. Sliding ventilators should be fixed in the walls near the bottom, and also near the eaves, and the openings covered with perforated zinc sheets. The most suitable store-room is one on the north side of a high wall or other building. Thatched sheds are very suitable, because the fluctuation of the internal temperature is less than in sheds tiled or slated. Medlars must be placed in single layers on shelves covered with sand. Nuts keep very well if stored in stone jars, and either buried in dry ground or covered with soil on the floor of a quite cold shed.

TREES AND SHRUBS.

A NOBLE FLOWERING SHRUB.

SPIRÆA LINDLEYANA, the noblest of all the shrubby Spiræas, is a native of the Himalayas, and sometimes, under favourable circumstances, attains a height of 15 feet. This is the height of the specimen shown in the accompanying illustration, its diameter being 18 feet. A large example in a well-chosen situation, backed by evergreens at some little distance, is, when producing its spreading panicles of ivory white flowers, an exceedingly handsome object. It possesses an additional charm in its graceful, pinnate leaves, which lend to the shrub, even when not in bloom, a highly decorative effect. It should never be relegated, as, unfortunately, is too often the case, to the crowded collection of heterogeneous subjects too often dignified by the name of "shrubby," where its roots are robbed of moisture by its hungry neighbours and crowded branches deny it the power to express its graceful symmetry.

When growing in proximity to water, as is the subject of the illustration, it exhibits exceeding vigour and speedily reaches a large size. It is towards the close of July, when its great white flower panicles are in perfection, that it attains the zenith of its loveliness. Then almost every fresh green spray is terminated by a spreading white plume from 18 inches to 2 feet in length, and a delightful picture is presented such as few inmates of the garden can rival. Indiscriminate pruning, which is too often indulged in, should be avoided. Many specimens which would otherwise reveal themselves in their true form are prevented from so

doing by being cut hard back yearly. All that is necessary is to cut out the weakly shoots and to shorten back old flowering wood to a strong bud. Beautiful as is the picture of this Spiræa in full bloom, it has, unfortunately, the demerit of being a fleeting one, and in this respect compares unfavourably with the blossoms of its American relative, *Spiræa aræfolia* or *discolor*, which retain their purity for a considerably longer period.

The subject of this note, with *S. aræfolia* and *S. flagelliformis*, also known under the names of *S. canescens* and *S. hypericifolia*, are three fine shrubby Spiræas that are well worthy of choice positions in the garden. Though delighting in leop and moist soil and never so happy as when growing by the water-side. *S. lindleyana* often seeds freely, and in many cases large specimens may be found surrounded by young self-sown seedlings. WYNDHAM FITZGERBERT.

THE GREENHOUSE.

SEASONABLE NOTES ON CHRYSANTHEMUMS.

IF will be advisable to carefully examine toward buds at least twice every day, and so watch for the showing of the colour of the flower-petals. Directly they show colour, or even if the scale in the centre bursts and exposes to view the points of the petals, the plants must be placed in the greenhouse, Peach-house orinery, whichever is most convenient. The first plants to house will be those naturally late flowering, the buds on which will be quite forward now if taken early in August, and a few of the naturally early flowering sorts, which

pruned back, or a Peach-house, the plants may be placed in single rows. Probably there will be room for them on both sides of the path. In a lean-to house the tall plants might be arranged in a row near the back wall, with a row of dwarf-growing plants in front. In such cases three rows of plants can be arranged, and they generally do remarkably well. In the case of a very small house, only the very best plants should be put in. A temporary shelter can be put up against a wall for the protection of the remainder, as cultivators often grow more plants than they can find room for under glass in the autumn. A current of air passing through the house will not be harmful, but beneficial, during the week or ten days following the placing of the plants under cover. At the end of this period ventilation must be ample, without cold

draughts blowing directly on to the foliage, else the latter will soon become badly mildewed.

Timing Blooms.—Many inexperienced cultivators would like to know how long a bud takes to develop into a full-centred flower. A naturally late-flowering sort belonging to the Japanese section requires a little more than six weeks from the date when the points of the petals can be clearly seen. If we take *Frances Jolliffe* as an example of a medium early-flowering variety, five weeks are required. In order to get well-built, full-centred blooms of late sorts of the incurved section, six weeks must be allowed. The very early ones will open in about four weeks, and some of the single-flowered sorts in rather less time still. During the first stages of the development of the bloom, progress seems slow, and, indeed, it is compared to the progress made after the flower is half open. It is better to give every bud proper

time, rather than be obliged to force backward blooms just prior to the date of the show. AVON.

THE DAFFODIL AS A POT PLANT.

BEAUFIEUL and useful as are Tulips and Hyacinths, I think that when well grown the Daffodil even eclipses these favourites as a pot plant. Forcing, as it is generally understood, the Daffodil will not stand, especially in the earlier stages of growth; but by the exercise of a little care very fine flowers may be had several weeks before they appear out of doors. When required for pot culture, the very best selected bulbs should be purchased. These are a few shillings per hundred dearer than ordinary stock, but will produce 25 per cent. to 50 per cent. more flowers, and these of very fine quality. The bulbs may be potted up at any time from August to October—the earlier the better, as a rule. Select 6-inch and 7-inch pots, and

SPIRÆA LINDLEYANA IN A DEVONSHIRE GARDEN.

despite the careful manipulation of the shoots by the cultivator, will have borne buds somewhat early. It is worse than useless to leave such buds exposed to rams and night dews, as they would quickly decay. Small buds containing only a few flower-petals would not be damaged by such exposure, but the large, fat buds would retain the collected moisture near the base of the petals, and early decay would set in there.

The House Facing North.—Of course, amateur cultivators do not always possess glass structures from which a selection may be made suitable for the accommodation of these plants. If, however, there is a house facing the north and not unduly overshadowed by trees or buildings, it will be a capital one in which to place the plants, as the latter require shelter but plenty of light and air without exposure to strong sunshine. In an earlyinery where the Vines have been partially

allow a fair quantity of drainage. The soil should be of good quality, but not over-rich. A good medium is best fibrous turf, three parts; leaf-mould, two parts; sharp sand, one part. No manure should be used, but a 6-inch pottol of bone-meal to each barrow-load of compost is very beneficial.

In potting, try to leave the compost rather loose under the bulbs, but quite firm on the surface. The tops of the bulbs should not be quite covered with the potting soil. After potting, water well; then stand the pots closely together on a hard bottom out of doors and plunge in sand, or even old cutting soil. Ashes, unless they have lain exposed for a couple of years, should not be used, for the sulphur present in fresh ashes is very harmful to young vegetation. Daffodils should be left in the plunging material for quite three months. At the end of that time they should be placed in a cold frame with the sashes well matted for a week or ten days. Afterwards admit plenty of light and air, and at the end of three or four weeks

the appearance of a head with very long, dishevelled hair, which induced the late Dr. Lindley to call the plant the Medusa's Head Orchid. It is a native of Singapore, and is sometimes known as *Cirrhopetalum Medusæ*, being first introduced by Messrs. Loddiges of Hackney in 1841. Bulbophyllums are for the most part more interesting to the botanist than to the Orchid fancier, but the one named *B. barbigerum* never fail to attract attention. Their dwarf habit and preference for a light and airy position render them suitable subjects for Teak-wood baskets, so that they can be suspended from the roof of the warm house. A suitable compost consists of *Osmunda fibre* and sphagnum moss. During active growth a humid and warm atmosphere is essential, but while at rest cooler surroundings are preferable. S.

LILIUM SPECIOSUM.

The practice of retarding Lily bulbs which is at the present time so extensively carried out

Now, immense numbers reach us from Japan, and, as a rule, in very fine condition. The state of these Japanese bulbs shows that they have been grown under very congenial surroundings, and they can be depended upon to yield most satisfactory results the first season after planting or potting. The variety among them, too, is numerous, some of the coloured kinds being particularly rich. One of the brightest of all is *Melpomene*, whose flowers are of a bright carmine crimson colour, with a white margin.

The bulbs of the best coloured forms are, as a rule, irregular in shape, and have a tendency to produce many stems. So marked is this feature that in sorting over large quantities of bulbs I have never had any difficulty in selecting most of those that would give the richest-coloured flowers. There are some whose blossoms are of a rose tint, corresponding with the *roseum* and *rubrum* of the Dutch; but, generally speaking, the bulbs from Japan represent a deeper-tinted class of flower than those from Holland. The Japanese variety *Krætzeri*, which, by the way, is often sent here under the name of *album*, is widely removed from the *album* which has been grown in Europe from the first. In the *album* of old, and still grown by the Dutch, the bulbs are of a dark chestnut colour, and the stems, leaf-stalks and unopened buds tinged with chocolate. The interior of the flower is white, with occasionally a very slight pinkish suffusion. On the other hand, the bulbs of *Krætzeri* are yellowish, with stems and leaf-stalks green, the unopened buds, too, being of the same tint. The flowers are large, far more regularly reflexed than those of *album*, and with a greenish star at the base of the interior. The anthers of both of these varieties are chocolate. One, which reaches us in a limited number from Japan, has bright yellow anthers. This, which bears the name of *album novum*, is, except for the distinguishing anthers, much in the way of *Krætzeri*. Fasciated forms, in which the flowers are borne in a large head or cluster, are not much grown now, though at one time they were sent here from Holland in considerable numbers. However, their absence is no loss.

In order to have flowers of *Lilium speciosum* for the greenhouse or conservatory in August or September, the bulbs should be potted about February, giving them but little water till the roots are active. When potted they may be stood in a frame from which frost is just excluded, or they can be placed out of doors and have one or two mats thrown over them in the event of sharp frost. In this way they will grow sturdy and not come into flower before their normal period, two, in a general way, very important matters. In potting, a good-sized bulb will need a pot from 6 inches to 7 inches in diameter, while large clumps or masses can be formed by putting several bulbs in a large pot or tub. In potting *Lilium speciosum* it should be borne in mind that it is one of those Lilies that develop a great number of roots from the base of the flower-stem and just above the bulb. For this reason space must be left when potting for a liberal top-dressing as soon as these roots are sufficiently advanced to enable them to obtain nourishment therefrom. During the growing season, all that these Lilies need is to keep them well supplied with water and to give an occasional stimulant as the pots get furnished with roots. Unlike *L. longiflorum*, aphides or green fly rarely trouble *L. speciosum* to any extent. The plants may be left out of doors till the flowers are on the point of expanding.

H. P.

THE MEDUSA'S HEAD. AN ORCHID OF SINISTER APPEARANCE.

remove to a cool greenhouse. Use no more heat than just enough to repel frost. When flower-buds show a little, more warmth will do no harm; but at no time attempt forcing. When in full growth, a mild stimulant should be given twice a week. While quite a number of Daffodils succeed well in pots, the following are always reliable: *Victoria*, *Emperor*, *Golden Spur*, *Henry Irving*, *Sir Watkin* and *Mme. de Graaff*. C. BLAIR.

Preston House Gardens, Linlithgow.

THE MEDUSA'S HEAD ORCHID.

(*BULBOPHYLLUM MEDUSÆ*.)

This curious plant was exhibited at a recent meeting of the Royal Horticultural Society by E. de L. Quincey, Esq., Oakhurst, Chislehurst, when he received a cultural commendation for a specimen with seventeen heads of its quaint flowers. These are small, but numerous, and are produced in a dense cluster at the apex of the scape. The lateral sepals are lengthened so as to give the spike

(enables one to obtain flowering examples of this Lily at any season of the year. It is for retarding purposes one of the best, as the bulbs are rarely affected by this mode of treatment, and will start away freely as soon as placed under conditions favourable to growth. Bulbs that have been retarded are, however, more expensive than those purchased as they arrive from Japan, say, during the three winter months. What is more, if potted and allowed to come on in a natural manner they bloom at a time when many of the summer-flowering occupants of the greenhouse and conservatory are over or, at all events, on the wane, and good examples of this Lily therefore furnish a pleasing variety. *Lilium speciosum* was first introduced into Europe from Japan about eighty years ago, and soon became generally distributed. It was taken in hand by the Dutch cultivators of bulbs, and has been largely grown by them ever since; indeed, until the Japanese took to sending bulbs of it to this country, the whole of our stock of *Lilium speciosum* was imported from Holland.

GARDENING FOR BEGINNERS.

HOW TO LIFT AND STORE POTATOES AND OTHER ROOT CROPS.

AFTER bestowing every care on the growing crops throughout the season, it would be very unwise on the part of the cultivator to neglect them when matured or in a fit condition for harvesting. Not only must the roots be lifted at the proper time, but stored also in the right way; then they will keep sound until all are used in the ordinary way.

Potatoes.—These undoubtedly form the chief crop, being used in summer, autumn and winter—practically the whole year round. The real work of storing commences when the main crops are lifted in September and October. There are several ways of storing the tubers; I will explain two, which will meet the requirements of the majority of cultivators. It is not always convenient to store all the tubers in buildings, so clamps are formed as shown in Fig. A at Nos. 1 and 2. In different parts of the country different names are given, such as Potato bogs, camps and pits. Only tubers intended for eating purposes should be stored in dark places. Select a dry position, one on raised ground, lay down some dry straw, then the tubers on it, building them up, as shown in the sketch, to a ridge. The base will be about four feet wide and the height three feet. Put on a layer of straw, then one of soil, about one foot thick, finally covering all with straw in thatch fashion. At distances of 6 feet apart, insert wisps of straw in the ridge, as shown; these will ensure ventilation and prevent sweating and decay. The soil used for covering will, if taken from the foot of the clamp, leave a channel, with the tubers above on a dry base. In buildings and sheds the tubers may be stored as shown at No. 3, with a padding of straw next to the wall and a simple covering of straw.

Storing Seed Tubers.—These should be exposed to the light and air, the choice ones in single layers

METHODS FOR STORING POTATOES FOR VARIOUS PURPOSES.

on shelves, as shown at No. 4, and those for main crops in double layers, as shown at No. 5. Nos. 6, 6, 6 show the right tubers to select for seed purposes, Nos. 7, 7, 7, 7 being the best ones for kitchen use. The smallest tubers are good for pigs and poultry, and must be stored separately. With these place all bruised tubers similar to the one shown at No. 8.

Other Kinds of Roots.—All roots must be lifted without undue bruising. Fig. B, at No. 1, shows a Beet fitted, and at No. 2, trimmed ready for storing. This is done by simply twisting off the

tops—the leaves. No. 3 represents a Carrot trimmed ready for storing, and Nos. 4 and 5 Onions in a fit condition to "rope" or bunch. No. 6 shows a useless bulb. No. 7 depicts a short stick which may be used for "roping," and No. 8 the "rope" complete and ready for suspending from the roof of a shed. The smaller bulbs are first tied to the stick, then the larger ones. Strong strands of straw, twisted, may be used instead of sticks on which to tie the bulbs.

Storing in Clamps.—Carrots and Beet may be stored in open-air clamps in much the same way as Potatoes. No. 9 shows the covering of straw on the layer of soil, No. 10, no inner layer of straw being necessary. Turnips will remain quite fresh for a long time if simply buried in the ground, as shown at No. 11. Pickling Onions, No. 12, will keep well on shelves in sheds safe from frosts. The shelf, No. 13, may be constructed of strong laths or half-inch mesh wire-netting. The Onions, No. 14, being in layers about six inches deep, will keep, as air can pass through the wire-netting to them.

G. G.

THE CARE OF CHOICE SHRUBS.

HOLLIES, Evergreen Oaks, Laurels and several other kinds of trees and shrubs cast their leaves during the summer months, and if the leaves are left among the grass, the latter soon becomes thin and coarse. Furthermore, the shrubs seem to suffer through over-dryness at the roots in the case of young specimens rooting in a limited area. At the present time all tall grasses must be cut and cleared away where they have reached the lower branches of the shrubs. We carefully feed our pot plants and many of those growing in borders, but often neglect to even water the shrubs, much less feed them. If they were fed and watered regularly when the soil approached a dry state, they would grow and form fine specimens in about ten years.

SHAMROCK.

ONIONS, CARROTS, TURNIPS AND BEET SHOULD BE STORED AS DESCRIBED IN TEXT.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Flower Garden.

Border Carnations layered early in August should now be in a fit condition for hitting and potting. Pot firmly and place in a frame with a good ash bottom.

Planting in Beds.—Where the soil is naturally light and dry, the young rooted layers may be planted in beds. The addition of a proportion of fresh loam, old mortar rubble and wood-ashes is a distinct advantage. Firm planting is necessary, and a sprinkling of soot or lime should be given to ward off slugs, not forgetting during the winter that sparrows pay the plants much attention, so that cotton should be placed over the plants as a preventive.

Pentstemons.—These are largely used for beds and borders, and should be propagated on similar lines to the *Calceolaria*, as advised in last week's calendar.

Antirrhinums also may be propagated now; but except where an absolutely true stock is wanted, propagation by cuttings is not necessary, as many of the varieties come well—over 99 per cent. true—from seed.

The Pleasure Grounds.

Lawns.—The past dry summer will in many instances have severely tried the grass, and it may be necessary, where it has been severely burnt, to break up the ground and re-sow. Where trees are not overhanging and it is not necessary to sweep two or three times a week, the present is a really good time to sow grass seed. Where only small patches need renovating, the surface may be well scratched with a rake or fork, adding a little fresh soil; but if large stretches have to be dealt with, more elaborate methods of working the ground must be employed. The old turf should be skinned off, and a good dressing of manure given to the ground as it is being forked over. Careful treading and levelling are quite necessary, as also is a very fine surface for sowing if the best results are to be obtained.

Plants Under Glass.

Chrysanthemums.—No time should now be lost in getting the whole of the large-flowering section under cover. Those that were placed inside as the buds showed colour should be nicely arranged in a cool house where they can be shaded. Those that are only fairly forward should be placed all together in another house, and the late ones also by themselves. In this way they can be advanced or retarded to suit the requirements of the establishment. Such an arrangement is even more necessary if they are being grown for exhibition. As the plants are housed they should be sprayed with sulphide of potassium as a preventive against mildew; also all pots should be scrubbed. Many of the later-flowering decorative varieties may be left out for a little time longer, but some arrangement should be made so that they can be covered in the event of frost.

Caladiums that have partially dried down may be removed from the stove to a warm pit to complete the drying off process, when they should be stored under the stages of the stove, or at least in a place where the temperature does not fall below 60° to 65°. There are more losses from storing in too low a temperature than from anything else.

Sweet Peas.—A sowing should now be made for early flowering under glass. Sow two or three seeds in a 3-inch pot in a fairly holding though porous soil, placing the pots in a cold frame where they may be covered in the event of very wet weather.

The Kitchen Garden.

Late Peas.—Despite the dry summer, late Peas still look well in some localities, and though these may not be expected to last much longer, every encouragement should be given to the plants to fill those pods that are already set. If the weather is still dry, give a good soaking of manure-water and pinch out the points of the shoots; this should help them considerably.

Dwarf Beans.—These are always in demand, and the crops coming into bearing in the frames

should be treated as liberally as the weather permits, it being of no use to feed the plants if the weather is such that they are not growing fairly freely. Climbing Dwarf Beans may be planted now in Melon or Cucumber houses from which the crops have been cleared, and with careful attention will give better crops and over a much longer season than the dwarf varieties. Late-sown batches out of doors that are still cropping nicely should be covered at night in the event of frost, as we often get one or two slight frosts at the end of September or early in October, and no more, perhaps, for two or three weeks.

Leeks.—This is a crop that needs a good deal of feeding, and the later batches should have one or two good soakings of manure-water or a sprinkling of artificial manure when it is raining. Specimen Leeks for November exhibition should receive their final earthing, just keeping the cardboard collars above the soil.

Fruits Under Glass.

Figs in Pots which have ripened their second crop of fruit should be relegated to the cooler houses, or even to a temporary shelter out of doors, where they may remain till the advent of severe frost necessitates their removal to a frost-proof house. Trained trees that are ripening their fruit must be kept moist enough at the root to prevent the foliage and fruit ripening prematurely, which they are apt to do at this season if allowed to get too dry. Fire-heat must be turned on towards the evening, and at all times when the weather is dull and wet, till all the fruit is gathered, when the trees should be gradually aired to plenty of air.

The Hardy Fruit Garden.

Gathering Fruit.—This should be continued as fast as the varieties become fit, but the late varieties of both Apples and Pears should be left on the trees as long as they will hang, or shrivelling will result. Fruit put inside a week or two ago should be carefully looked over, as those fruits that were only just touched by tits or wasps will be found decaying, and if left are apt not only to contaminate those all round them, but those underneath upon which they may happen to drip.

THOMAS STEVENSON,

(Head-gardener to E. Meatta, Esq.)

Woburn Place Gardens, Addlestone, Surrey.

FOR NORTHERN GARDENS.

The Flower Garden.

Single Rockets.—These sweet-scented plants, treated as biennials, are very telling when planted in masses. They are also very useful in the cut state for filling large vases in early summer. They vary a good deal in colour, and this year I saw a batch of a lovely rich purple shade. The present is a good time to plant them where they are to flower.

Planting Bearded Irises.—The present is a suitable time for planting this interesting and easily-cultivated class of Irises. Here we devote a border to them, with a few dot plants of such things as *Tritomas* and *Hyacinthus canalicatus* to keep up a bit of colour after the Irises have finished flowering. They are not very particular as to soil, provided the ground has been previously deeply dug and has received a moderate dressing of manure. Plant small pieces, as they soon increase, and do not plant deeply; the fleshy rhizomes should not be quite buried. A few plants of different varieties of *I. sibirica* at the back and some of the dwarf Bearded Irises at the front will redeem the border from monotony.

The Rose Garden.

Bengal Roses.—These are also known as China and Monthly Roses. They are, generally speaking, weakly growers, especially on cold, heavy soils. On this account we have discarded many varieties, and now only grow the following two beautiful sorts, each with sufficient vigour. They are *Mme. Laurette Messimy* and *Antoinette Guillerat*. *Queen Mab* and the *Old China Blush* have both plenty of vigour, but compared with the other two varieties indicated they are as silver to gold.

Baby Ramblers, or Polyantha Roses, are excellent for beds. *White Pet* is too well known to require commendation. *Jessie* and *Orleans Rose* are two good reds, and *Mme. N. Levayasseur* is a good third, in the way of *Crimson Rambler*.

The Shrubbery.

Hypericums.—With the exception of *H. calycinum* (*Rose of Sharon*) and *H. perforatum* (*St. John's Wort*), the *Hypericums* do not seem to be much taken advantage of for furnishing the shrubbery. The two indicated are good second-row and front-row plants respectively, but for the centre of a border the three following are excellent: *H. androsannum*, *H. Aseyron* and *H. kahuiamoo*, *H. pyramidatum* and *H. patulum* are also two good species suitable for the shrubbery.

Preparatory to Transplanting.—Where it is intended to move established subjects either during autumn or in the following spring, the operation will be performed more successfully if the roots are severed all round with a sharp spade at about eighteen inches from the stem.

Plants Under Glass.

Housing Chrysanthemums.—Plants grown for big blooms had better be got under glass without much further delay. The whole stock should, however, be sprayed as a preventive against mildew previous to being housed. *Molyneux's* antidote is unexcelled for efficacy. It is as follows: Place 2lb. of sulphur and 2lb. of unslaked lime in ten quarts of water and boil for twenty minutes. When spraying, use two wine-gallons of the mixture to four gallons of clean cold water. A solution of sulphide of potassium can be used if preferred. Give the newly-housed plants abundance of air day and night for a time.

Overhauling the Heating Apparatus.—As frost may occur at any time now, the whole of the heating apparatus should be inspected to see that all is in good order for the coming winter.

Fruits Under Glass.

Tomatoes in Frames.—Tomatoes in frames or other unheated structures, if not ripe now, will do little good where they are. The remainder of the crop should be picked and placed in a dry, heated structure, and those who can do no better can easily ripen them off on a kitchen shelf.

Winter Cucumbers.—Recently-planted stock for winter supply must have a brisk temperature, say, 65° minimum. Less moisture will now be required, but actual dryness must be guarded against, both in the soil and the atmosphere. As the female flowers appear, they should be artificially pollinated.

Decaying Grapes.—Wherever these occur, they should be promptly removed by means of the Grape scissors.

The Hardy Fruit Garden.

Harvesting.—This work will now be nearly completed, but unripe fruit should be left as long as the state of the weather will permit.

Storing Plums.—Plums have been rather a poor crop this season, but wherever it is desired to retain the fruit as long as possible, this can be done with the *Coe's Golden Drop* type by the following means: After keeping the fruits in a thoroughly dry place for a few days, wrap them in tissue-paper separately and keep in a dry place.

The Kitchen Garden.

Framing Cauliflowers.—Young plants, the result of the August sowing, should now be lifted and planted a few inches apart in a cold frame. Do not use rich soil. Nothing equals pure fibrous loam for this purpose. Pricked into this, the plants will lift with good balls of roots in spring. Close the frame for a few days and shade, and then keep the lights off whenever the temperature is above freezing point.

Storing Marrows.—Marrows will not do much more good now. Any fruits on the plants, however, if cut now and placed in a cool, dry pantry, will keep for a long time.

Lifting Potatoes.—The bulk of the Potato crop will now be ready for lifting. Tubers intended for seed should be stored in trays in a cool, airy shed. Tubers intended for cooking should be placed in a pit, but the top of the pit should not be covered with earth for a week or two till the surplus moisture has evaporated. CHARLES COMFORT.
Broomfield Gardens, Davidson's Mans, Midlothian.

ANSWERS

TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—*The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" column. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.*

FLOWER GARDEN.

NARCISSUS ATTACKED BY STEM EELWORM (*A. L. R.*).—The Narcissus bulb is attacked by the stem eelworm (*Tylenchus devastatrix*). This pest is very troublesome this year, and is liable to attack other bulbs which are planted in proximity to diseased ones.

LILIES OF THE VALLEY NOT FLOWERING (*Chalfont St. Peter*).—The reason of your Lilies of the Valley not flowering this year is in all probability that they were not sufficiently established for them to perfect their crowns for this year's blooming. If the soil is good and they have been well supplied with water during this abnormally dry season, you may reasonably anticipate a good display of bloom next season. The condition of the leafage will, however, give you a good guide as to this, for if the foliage is poor and scanty, you cannot expect a good crop of blossoms. If the leaves show any signs of starvation, a good plan will be to give the bed a top-dressing of some fairly rich compost, say, equal parts of loam and well-decayed manure passed through a sieve with half an inch mesh. This mixture may be put on to a depth of half an inch to an inch, according to the present position of the crowns.

PINK AND YELLOW PERENNIALS FOR JUNE AND EARLY JULY (*Miss J. C.*).—The flower sent for naming is *Astrantia major*, the Greater Masterwort. Good, bright pink and yellow flowers of the height you desire are rather scarce during the months of June and early July, but the following may be helpful to you: *Pink*—*Athaea canabina*, 5 feet to 6 feet; *Astrantia helleborifolia*, dull pink, 2 feet; *Centaurea dealbata*, 2 feet; *C. montana rosea*, 2 feet; *Incarvillea Olage* (not very hardy), 3 feet to 4 feet; *Lathyrus rotundifolius*, climbing, 4 feet to 5 feet; *Spiraea palmata venusta*, with some of the *Arenaria* hybrid *Astilbes*, such as *Vesta*, *Ceres*, with *Queen Alexandra* and *Peach Blossom*, which, it will grow, will reach over two feet. Some of the pink herbaceous *Paeonies* to be found in nurserymen's catalogues will answer well, and *Pyrethrums* will come in useful early in the period. Really good pinks are scarce, though there are plenty of scarlets and crimson. The following yellows are suggested: *Achillea Eupatorium*, 4 feet to 5 feet; *Achillea millefolium*, 2 feet to 4 feet; *Aquilegia chrysantha*, 2 feet to 3 feet; *Centaurea macrocephala*, 4 feet to 5 feet; *Coropsis grandiflora*, 2 feet to 4 feet; *C. lanceolata*, 2 feet; *Doronicum plantagineum excelsum* (keep this back by taking off spring flowers), 2 feet to 4 feet; *Hemerocallis*, almost any, omitting *H. fulva* and varieties and *H. aurantiaca major*; *Iris*—*Monnierii*, 3 feet to 4 feet; *I. aurea*, 2 feet to 4 feet; *I. sibirica dalmatica*, 3 feet to 4 feet; *Emothera Youngii*, 2 feet to 3 feet; *Potentillas*, yellow hybrid varieties, such as *Gold Kugel*, *Mont d'Or*, *Phœbeis* and *Vase d'Or*; and *Thermopsis montana*, 2 feet. Some good pinks will be found among the early section of *Phloxes*. *Chamæleon*, *Isaac House* and *The Queen* may be named. We prefer *Impatiens Sultanii*, which is a perennial and is propagated by cuttings of strong shoots put singly in small pots and placed in a propagating-frame. Dry sand is the best means of storing the roots of *Salvia patens* and *Camœlia cœlestis* for the winter.

TREES AND SHRUBS.

WISTARIA AND SECOND CROP OF FLOWERS (*St. Francis, A. Hay, Chesham*).—It is not unusual for a *Wistaria* to produce a second crop of flowers during late summer, although your plant appears to be blossoming more freely than most plants do at this period. The dry weather experienced during the last few months may account to some extent for the quantity of inflorescences.

CLIMBERS FOR POLES (*Rubus*).—The two *Roses* named would be very suitable; also the following sorts—*Amée Vibert*, *Alister Stella Gray*, *Bouquet d'Or*, *Celine Forestier*, *Climbing Devonians*, *L'Idéal*, *Rêve d'Or*, *Reine Marie Henriette*, *Mme. Alfred Carrière* and *Maréchal Niel*—should do well in your garden. Other suitable climbers are *Vitis* (*Ampelopsis*) *Henryi*, *Clematis* *Viticella* and varieties *alba* and *rubra*, *C. Jackmanni* and varieties *Snow White* and *superba*, *Forstythia suspensa*, *Jasminum nudiflorum*, *officinale*, *primulinum* and *revolutum*;

Pasiflora coriaria, and *Wistaria chinensis*, and variety *alba*. Any of the foregoing which grow too vigorously can be kept within bounds by using the knife freely. The *Crataegus* and *Berberis* are not suitable. *Pyris* (*Cydonia*) *japonica* would clothe the pole, but is not suitable to train along wires.

SHRUBS FOR NAME AND TREATMENT (*Bidd*).—The specimens sent for determination are as follows: 1, *Ceanothus Cereus*; 2, *Spiraea japonica* var. *Anthony Waterer*; 3, *Spiraea japonica* var. *alba*. All may be propagated by means of cuttings of half-ripe shoots inserted in sandy soil in a close, shaded frame during July and August. Cuttings inserted at the present time may take root, but as a rule they prove more satisfactory at the earlier date.

BLACK BLIGHT ON TREES (*G. M. G.*).—The black blight of which you complain is the result of the leaves being infested with aphides earlier in the year. The insects deposit a sticky excrement on the leaves, which are afterwards in a condition to collect and retain dust and other impurities of the atmosphere. The fact of shrubs covering the ground beneath affected trees accounts largely for so many varieties being infested. Probably had some of the subjects been growing in the open garden, they would have escaped. Evergreens may be cleaned to some extent by lightly syringing the leaves and branches with strong soft soapy water. Then, before they have time to dry, hose them with a strong force of clear water. It is better, however, that such work should be done earlier in the year, before the covering has become so dense.

FRUIT GARDEN.

SPOTS ON ALICANTE GRAPES (*J. H.*).—Your Grapes are suffering from a disease which in garden parlance is termed "scald." It is caused by too cold a temperature and too damp an atmosphere. To cure it, add brick-heat to the hot-water pipes, give an freely all day, and some at night, too, when the weather is favourable. Do not have the vine quite closed up at any time in any weather. Free ventilation, with a fair degree of heat in the pipes, should stop the spread of the disease and help to ripen your Grapes in due time.

FIGS NOT RIPENING (*E. M.*).—You do not say whether your Fig tree is growing against a wall or not. Figs in the open ground round Ealing will not ripen satisfactorily except in very hot summers. If your tree is growing against a south wall, there is no reason why the fruit should not ripen if the tree is properly looked after. Your fruit, which you say is at present dry, may yet ripen in the course of next month. Out-door Figs are not yet ripe. Expose the fruit to more light and air by tying the branches and foliage on one side.

VINE LEAVES FALLING PREMATURELY (*Curious*).—The case you state is an uncommon one, but we have occasionally experienced the same thing. It is due, we think, to conditions of weather and growth rather than to any disease, and we think you will find that the Vines next year will suffer practically no ill-effect from the occurrence, especially if you will try to encourage a new lateral growth from what there is left of the summer growth, in order to properly develop and plump up the fruit-logs. The summer, on the whole, has been wanting in sunshine, and the growth, especially of young Vines, has been robust, soft and sappy, with often a lot of moisture hanging about them. This, we think, must have been so in your case, and occasional intensely hot gleams of sun striking off the foliage at the time when the Vines were in this condition was too much for them.

PEACH STONES DECAYING (*On Town & Nonconformist Enquiries*).—The real cause of stone-spitting and consequent decay of the stone is a subject on which, as far as we know, no specific or definite information is available. The disease seems to have a partiality for some varieties over others, notably late varieties of large size, such as *Lord Palmerston*, *Princess of Wales*, *Sea Eagle* and sometimes *Noblesse*. The disease also, according to our experience, appears to attack the fruit more frequently in unheated peach-houses than in heated ones or out of doors. We believe the cause to be due to some imperfection or fault in fertilisation, which ultimately develops into this disease. We are fortified in this opinion by the fact that we practically got rid of it on one occasion by adding hot-water pipes to the house, thereby creating a warmer, drier and more favourable atmosphere for setting the fruit while the trees were in bloom. We believe, also, that the trouble may, partially at any rate, be got over by taking special care to have abundance of air admitted to the house night and day while the trees are in bloom in favourable weather, and to protect from hard frost (glass alone is not always enough for this), aided by artificial fertilisation. Some growers think that the trouble is due to insect pests, such as ants or earwigs. These insects are generally attracted to these fruits when affected by this disease, penetrating into them through an orifice in the flesh at the base of the stalk, which usually accompanies this disease. We do not think the insects have anything to do with the cause of it.

KITCHEN GARDEN.

MARROWS UNSATISFACTORY (*O. I. C.*).—Imperfect fertilisation of the blooms is the cause of the young Marrows rotting at the point as you describe. Watch for the female blossoms as they appear, and expose to more light and air (until the Marrow is set) by pushing on one side a few of the grosser leaves until this process is over. Marrows do not like too much wet about their foliage or roots.

At the same time, they must always be kept moderately damp at the roots. There are many complaints of Marrows doing badly this year.

MISCELLANEOUS.

A NEW AZALEA DISEASE (*Chesham*).—The *Azalea* is attacked by the fungus called *Exobasidium japonicum*, which produces galls on leaves and buds of *Azalea indica*. It is of recent introduction into this country, and spreads by means of spores, which form the whitish powder on the surface of the galls. They should be picked off and burned as soon as they are noticed.

HOW TO MAKE LIQUID MANURE (*Ignoramus*).—Various quantities of manure may be immersed in water. One peck of cow or two pecks of horse manure may be placed in a bar, and the whole immersed in twenty gallons of clear water in a tub or other vessel. It should be left to soak there for three days, being moved to and fro a little twice every day. Use one pint of the liquid to a gallon of clear water, and a similar quantity of the cow-horse liquid to a gallon of clear water. Both soot-water and liquid manure should be applied at rain or a watering of clear water from the watering-can.

MAGNOLIA AND PELARGONIUMS (*Everest Langman*).—Your *Magnolia* is apparently the *Everest* species, *M. grandiflora*, and you may carry out the necessary amount of pruning at once. Cut the branch off carefully so that the bark on the adjoining part of the tree is not injured, then pare the edges of the wound with a sharp knife, and cover the wounded surface with coal-tar without delay. Your *Pelargoniums*, which are infested with mealy bug, may be cleaned with a wash made of soft soap and paraffin at the rate of half a pound of soft soap and half a pint of paraffin to three gallons of water, keeping the mixture well stirred while in use; or with any of the insecticides supplied by nurserymen. Keep the plants isolated for a couple of months, and clean them at least once a fortnight during that time. The mealy bug ought to have disappeared entirely before the end of the two months.

SLUGS IN A MORAINÉ (*H. E. T.*).—It is most unusual for plants in a moraine to be devoured by slugs, and we know several gardens in which there are a good number of slugs about the rockeries, but none trouble the plants in the moraine. It is possible that they may have come with the material for the moraine, and as hand-picking, which is the most effectual way of destroying them in most cases, cannot well be adopted, we suggest occasional dustings with freshly-slaked lime in the evenings after dark when they are about. This should be repeated several times, with but a short time between the applications. A solution of ammonia is also suggested by some to destroy slugs, but it should not be strong. You might try bait in the form of bran, or Lettuce or Cabbage leaves, examining these after dark and destroying the slugs found on them.

NOTES ON THE ORDER VERBENACEÆ (*A. L. Orlows*).—The Order *Verbenaceæ* derives its name from one of the principal genera (*Verbena*) included therein. The chief members of it are of wide geographical distribution over the surface of the globe, and vary from humble herbaceous plants to tall forest-trees. To give the history, species and culture thereof would occupy far more space than we have available, but at the same time we will endeavour to comply with your request as far as possible. The garden varieties of *Verbena*, that is to say, those that are chiefly employed for summer bedding, have originated from some South American kinds which were introduced during the first half of the nineteenth century. These are very readily increased by seeds or cuttings. *Lippia trifoliata* is the well-known Lemon-scented *Verbena*, and is also known as *Alrosta trifoliata*. The principal species of *Vitex* is *V. Aemula*, native of Southern Europe and known popularly as the *Chaste Tree*. This is derived from the fact that it was largely used by the Roman monks for the embellishment of their apartments, it being regarded as a sign of their chastity. It thrives best in this country, trained to a wall, where it forms a loose-growing shrub, which, towards the end of the summer, bears spikes of very pale mauve, almost white, blossoms. Prominent among other genera that are included in the Order *Verbenaceæ* are: *Cherodendron*, an extensive class of warm-house plants, some of them being shrubby, while others are of a climbing character—the flowers of most of them are showy; *Calceolaria*, the best-known species of which is *C. purpurea*, a greenhouse plant which bears a great profusion of small purple berries in autumn; *Petrea*, one member of which (*P. volubilis*) requires the temperature of a stove and has long, drooping racemes of blue-coloured blossoms; *Lantana*, pretty free-flowering greenhouse plants, very popular now for bedding purposes; and *Caryopteris Mastacanthus*, a hardy shrub that thrives best in a warm soil. Its spikes of pretty blue flowers are freely borne in early autumn. From an economic standpoint the most valuable of all *Verbenaceæ* plants is the *Teak* (*Pterocarpus grandis*), a deciduous tree attaining a height of 120 feet to 150 feet, with a girth of 20 feet to 25 feet. It is a native of India, Burmah and the Malay Archipelago. The timber is extensively employed for ship-building, and is also put to a variety of other uses.

NAMES OF PLANTS.—*J. W., Forsyth*.—*Saponaria officinalis* flare plene. —*T. Day*.—The variety is not *Tea Rambler* but *Bausenschen*.

NAMES OF FRUIT.—*B. J. B.*—1, *Mugil*; 2, *King of the Pippins*; 3, *Yellow Ing-stre*; 4, *Lower of Glams*; — *E. E., Old Southgate*.—2, *Bennet's du Canada*; 5, *Hawthornden*; 8, *Arlington*; 13, *Ribston Pippin*. All the other labels were detached. Each fruit should be wrapped separately in paper with number enclosed.

MOSS ON PATHS (J. H. R.).—The moss on your walks is evidently caused by want of drainage. If you could put a drain below, you would probably get rid of it; but, as you may not wish to do this, you can try a top-dressing of lime, or of soot and salt, or lime and sulphur. Some also try a solution of ammonia sulphate in the proportion of half a pound to a gallon of water. The only other thing we can suggest is to keep the surface constantly loose; but this is not pleasant for a walk. Drainage is really the best cure.

PRUNUS AND GOLD-FISH (Captain E. F. O.).—*Prunus serrulata* *Bore plena* is stocked by Messrs. Veitch, King's Road, Chelsea, and is priced at from 1s. 6d. to 2s. 6d. a plant. They, however, call it *Cerasus serrulata*. It is not likely that gold-fish would survive the water in an outdoor tank of the dimensions you describe. They could, however, be placed in it for the summer. A Water Lily placed in the tank would be an advantage. Charcoal assists in keeping water sweet, but its presence does not do away with the necessity of a frequent change of water.

PARAFFIN TO KILL INSECTS ON MANURE (N. E. L.).—The amount of harm done by the paraffin poured on the manure to the plants subsequently to be grown would not be likely to be very great if some time elapsed between the treatment and the use of the manure; but it would be likely to interfere with the proper decay of the manure in the heap. Why not cover the heap with a layer of garden soil? Sulphate of ammonia for the treatment of a lawn should be used at the rate of 15wt. to the acre. For a lawn 100 feet by 50 feet, 18lb. to 20lb. would be sufficient; more should not be used.

LEAF-MOULD FOR HEAVY SOIL (Ljor).—In our opinion you may safely use the leaf-mould for lightening your very heavy soil, but at the same time we should reject any of the Pine leaves that you possibly can. This does not mean that you are to take extraordinary precautions to sort them out, but rather to give preference to the leaf-mould from spots where the Pine leaves are least numerous. As clayey soil is greatly benefited by breaking up and turning, we should advise that the leaf-mould be applied this autumn and well dug in; then in the spring, before planting, it should be again turned over and well broken up. The name of the Orange Lily is *Lilium croceum*, a very fine border Lily, at its best, as a rule, during the latter part of June and the first half of July.

LETTUCE FOR WINTER IN FRAMES (J. Rj).—The best varieties to grow for this purpose are the Standard Park Cabbage Lettuce and the Black-seeded Bath Cos. The seeds should be sown at once (it would have been better had they been sown a fortnight ago) in a cold frame in fine, light, friable soil, keeping the lights off the frame as long as the weather is fine. As soon as the young plants are 2 inches high, transplant into other frames (previously prepared as to soil like the other) 8 inches apart each way. Let the plants be exposed to the weather day and night while it is favourable, as the harder the plants are grown the better they will stand the winter. The seedling plants in the frame should be thinned out to 8 inches apart. Should there be any plants left over after planting the frames, let these be planted in the open quarters of the garden at the same distance apart as in the frames. These will survive the winter, unless it should prove to be very severe, and turn in early and useful in spring. During severe weather in winter those which are in frames must be protected with mats or some other covering material at night; but they must have fresh air every day if possible, or they will damp and rot away.

SOCIETIES.

ROYAL HORTICULTURAL SOCIETY.

IN addition to the usual fortnightly exhibition, there were competitive classes for vegetables and Dahlias at Vincent Square, Westminster, on Tuesday last. The hall was filled throughout, the vegetable classes being well contested, while massive banks of Dahlias and Michaelmas Daisies created bright autumnal colour scenes. It was pleasing to see Mr. John Heal back again after his long illness.

FLORAL COMMITTEE.

Present: H. B. May, Esq. (chairman), and Messrs. G. Benthley, W. P. Thomson, J. W. Mooriman, C. T. Drury, W. J. James, C. E. Pearson, G. Gordon, J. Green, E. A. Bowles, H. J. Jones, A. Turner, T. Stevenson, J. J. Bennett-Poe, B. Hooper, C. Penson, W. Howe, W. Cuthbertson, F. Page-Roberts, W. G. Baker, J. W. Barr, B. Crisp, J. Jennings, W. C. Neufitt and C. Dixon.

Mr. Ernest Ballard, The Cour, Colwall, Herefordshire, staged a fine lot of seedling Asters, all raised at Colwall. Numerous double-flowering varieties were shown, of which *Clauy Blue*, *Nancy Ballard*, *Glory of Colwall* and *Beauty of Colwall* were all grand. Some of the finest seedlings were unnamed.

Another grand exhibit of Asters came from the Wargrave Farm, Limited, The Arcade, Liverpool Street, E.C. This exhibit contained such fine varieties as *Amellus*, *Stella*, *Aris*, *Beauty of Colwall* and *Saturn*, while the small-flowered *ericoides*, *Chlo. cordifolius*, *Ideal* and *Virgin Queen* were shown in the height of perfection.

Messrs. Stuart Low and Co., Bush Hill Park, Middlesex, showed their new Salmon King Carnation, of good form and delightfully fragrant, together with *Enchantress*, *Supreme*, *Empire Day* and other well-known varieties.

The Rev. J. H. Pemberton, Havering, Essex, showed his new seedling *Roses*, *Diana* and *Moonlight*, both of which have often been referred to in our pages.

From Herbert Chapoian, Limited, Rye, came a lovely seedling *Nerine* named *Rotherside*, with fine orange red flowers.

Messrs. William Cuthbush and Son, Highgate, N., put up a first-rate collection of Pentstemons, of which *Mary Queen*, *Mrs. Baird* and *Pink Pearl* were the pick.

From Mr. James Box, Lindfield, came the beautiful *Lilium sulphureum* and *L. nepalense*, also *Cimicifuga simplex* and *Crimm Powellii*, making a very interesting though small exhibit.

Paloxes were shown in great profusion by Messrs. W. Wells and Co., Limited, Merstham, Surrey. The most conspicuous varieties were *Elizabeth Campbell*, *Edinburgh*, *Le Mahdi* and *Aurora*.

Messrs. Alwood Brothers, Hayward's Heath, showed Carnations in bright and perfect condition. The variety *Mary Alwood* was especially good, while the novelties *Yellowstone*, *Fairmount*, *Enchantress*, *Supreme* and *Rosette* are certain indications of the immense improvement among these flowers in recent times.

DAHLIAS.

In Class A, for amateurs, a group of decorative garden Dahlias of all or any section, 12 feet by 3 feet, was required, and there were three entrants. The first prize of the Royal Horticultural Society's silver cup and the Veitch Memorial Medal was won by the Rev. Arthur Bridge, Worth Rectory. Three *Brides*, *Sussex*, who put up a grand display. A few of his best blooms were *Queen Thomas*, *Leslie Seale* and *Rosebank Scarlet*, all *Collarettes*; while a fine reddish *Cactus* variety was named *Mary Purrier*. A second prize was awarded to Sir Randolph Baker, Bart., Blandford, for a meritorious exhibit; and the Duchess of Albany was the other exhibitor.

In Class B, a group of decorative garden Dahlias of all or any sections, 25 feet by 3 feet, was required, the prize being the 75-guinea challenge cup presented to the Royal Horticultural Society by Reaumur Cory, Esq. Here competition was very keen, there being eleven entrants. The first prize was, however, awarded to Messrs. Carter Page and Co., London Wall, E.C., for a superb display, in which all sections were well represented. The following were noteworthy: *Collarettes*—*Neara* and *Union Jack*; *Cactus*—*Mrs. D. Fleming*, *Australian* and *Amos Perry*; *Decorative*—*Délicie*, a beautiful rosy pink, and *Mme. Lamière*; *Peony-flowered*—*Bayard*; and *Pompon*—*Red Indian* and *Chiefman*. Following very closely were Messrs. J. Cheal, Crawley, who presented a splendid lot, one named *Victoria* being exceptionally good. Other entrants were Messrs. Dobbie and Co., Edinburgh; Mr. J. Emberson, Waltham-stow; Messrs. Treseder, Cardiff; Messrs. Warnar and Co., Sassenheim, Holland; Messrs. Keynes, Williams and Co., Salisbury; Mr. J. T. West, Brentwood; Messrs. T. S. Ware, Feltham; Mr. C. Turner, Slough; and M. V. Seale, Sevenoaks.

Non-competitive groups were few, and the best exhibit came from Messrs. Dobbie, Edinburgh, whose stand contained *Collarettes* only. They were in the pink of condition, and *Gold-stem*, *Queen Anne*, *Balmoral*, *Negro*, *Great Orange* and *Diadem* were especially good.

Mr. J. R. Ridin, Chingford, put up a nice lot of blooms, *M. Capron*, *Mont Rose*, *Negro* and *Water* being conspicuous.

Messrs. J. Barrett and Co., Cambridge, had eight vases of *Cactus* varieties, the one named *Moreno* standing out conspicuously.

ORCHID COMMITTEE.

Present: J. G. Fowler, Esq. (chairman), Sir Harry J. Veitch, Sir Jeremiah Colman, Bart., Messrs. James O'Brien, J. W. Potter, R. G. Thwaites, F. J. Hanbury, A. McBean, T. Armstrong, C. H. Curtis, W. Colby, J. Charlesworth, W. H. Hatcher, J. Cypher, W. P. Bound, J. E. Shill, H. G. Alexander, A. Dye, W. H. White, W. Flory, R. A. Rolfe, W. Bolton, Garney Wilson and C. J. Lucas.

In the pretty group set up by Messrs. Cypher of Cheltenham we saw several fine *Cypripediums* for which the firm is famous. They included *Gaston Bultel*, *Reiders Buller*, *Niobe*, *Corona*, and *triumphans*. *Cattleya Iris* was good, and a conspicuous plant was *Oncidium meivium album*.

Messrs. Armstrong and Brown, Tunbridge Wells, were represented by *Cattleyas* and *Odontodas*, the former embracing several fine varieties of *Iris*, and a few good *Laelio-Cattleyas*, of which their *George Woodhams* was specially noteworthy.

Messrs. Sander and Sons, St. Albans, displayed a varied exhibit which was rich in *Cattleyas* and *Laelio-Cattleyas*, also the choice *Coloeyne mooreana*, *Vanda cerulea* and *Pseudanopsis Esmeralda*.

From Messrs. Charlesworth came a few well-grown examples, such as *Laelio-Cattleya callistozlosa*, with seven nice flowers; *Oncidium meivium*, with an aggregate of eight graceful sepals; *Odontoglossum xanthotes* and other good things.

Messrs. Hassall and Co., Southgate, had a nice lot of *Cattleyas*, their varieties of *Adula* and *Iris* being very effective.

H. S. Goodson, Esq., Putney, sent a large exhibit, very tastefully arranged. It consisted of good *Laelio-Cattleyas*, such as *Myra*, also *Cattleya pittana* and *C. Iris*, while *Odontoglossum grande* was displayed along the front.

FRUIT AND VEGETABLE COMMITTEE.

Present: A. H. Pearson, Esq. (chairman), and Messrs. J. Cheal, W. Bates, J. Basham, J. Willard, Edwin Beckett, W. Humphreys, A. Grubb, A. R. Allan, William J. Jellies, J. Davis, W. Pope, E. G. Treseder, A. Barlock, G. Reynolds, P. A. Tucker, P. C. M. Veitch, J. Harrison and W. Pompari.

In addition to the well-filled competitive classes, there were a great many exhibits of more than usual interest not for competition. Seldom, if ever, have we seen a finer lot of vegetables than the comprehensive collection staged by Messrs. Sutton and Sons, Reading. To this magnificent display the society's gold medal was deservedly

awarded. Almost every conceivable kind of vegetable was represented. Roots such as Onions, Carrots and Parsnips stood out conspicuously, while Cucumbers and Tomatoes in great variety were shown in the same height of perfection, and the foliage of Kale and Beet added materially to the general effect of the collection, which was staged with a masterly hand.

The Right Hon. Colonel Mark Lockwood, M.P., Romford, sent a most interesting exhibit of Egg Plants, or Aubergines. These were shown in pots, the plants being heavily laden with white, purple and yellow fruits. A cultural commendation was granted to the collection, together with the society's silver Knightian medal.

Messrs. Dickson and Robinson were awarded a silver Knightian medal for a meritorious exhibit of their well-known Premier Onion. The bulbs were of fine size, even, uniform and quite firm.

A silver Banksian medal was awarded to the Marquis of Ripon for a good collection of Apples.

A Bronze Knightian medal was awarded to Mr. J. H. Potter, Malden, Surrey, for six dishes of Apples.

A creditable collection of vegetables from the Church Army received the society's silver Banksian medal.

In Class 1, for twelve distinct kinds, the Hon. Vicary Gibbs was first with splendidly-grown examples, the Potatoes *Superlative* and *Peas Centenary* being excellent. Mr. T. Jones, Ruabon, came second; Mr. F. J. Barrett third; and Mr. H. Kepp, Reading, fourth.

In Class 2 the judges did not consider that the conditions set forth in the schedule, *i.e.*, that the vegetables should be in daily use, and possess the qualities most valued for table use by cooks, were complied with, so no award was made. It is difficult to understand the attitude of the judges, as, with the exception of the Carrots in each class, the produce was quite suitable for cooking. The dishes of Gladstone Peas were splendid, and although the Beans and Onions were large, they were of excellent quality.

In Class 3, Brodie Henderson, Esq., Little Berkhamsted, led the way with clean and well-grown examples. T. Bibby, Esq., Shrewsbury, was second; the Right Hon. T. F. Halsey third; and Mrs. Trevor Goff, Basingstoke, fourth.

In Class 4, the Rev. T. McMurdie, Weybridge, secured first place; Mrs. Demison, Berkhamsted, second.

In Class 5, Mr. G. Thorn, Ashford, Kent, was first; and Mr. H. W. Henderson, King's Langley, came second.

In Class 6, Mrs. Jenner, Cardiff, was awarded first prize, exhibiting *Excelsior Onion*, &c., in good condition; the Hon. Vicary Gibbs was second, and W. H. Myers, Esq., Bishop's Waltham, third.

Classes 7 and 8, for salads, attracted attention from visitors, and in the former the Hon. Vicary Gibbs led the way, followed by Mr. Jones, Ruabon; and in the latter W. H. Myers, Esq., came first; Brodie Henderson, Esq., Little Berkhamsted, was second; and Lord North third. The Endive and Lettuce were very good.

Class 9 was most interesting, and the Hon. Vicary Gibbs gained premier position with dishes of *Salsify Giant*, *Capucium Golden Dawn*, *Scorzenera*, *Kohl Rabi*, the *Egg Plant* and *Turnip-rooted Celeria*. Lord North was second, and W. H. Myers, Esq., Bishop's Waltham, third.

There was a good display of Runner Beans (single dishes) *Beetroot*, *Brussels Sprouts*, *Cabbage*, *Savoys*, a few *Cauliflower* and *Broccoli* and *Celeriac*.

Celery was well represented, the Hon. Vicary Gibbs gaining first prize for white, Mrs. Lewis Davis coming second, and Mr. Barrett third in the same class. For red the Hon. Vicary Gibbs was again in the front, Mr. B. Kepp second, and W. H. Myers, Esq., third.

Several brace of Cucumbers, Marrows, Leeks, Parsnips, Carrots, Turnips and Potatoes completed a most interesting competitive exhibition.

ORCHID COMMITTEE'S AWARDS.

Silver Flora Medals.—Messrs. Charlesworth and Co., Hayward's Heath, for a group of Orchids; Messrs. Armstrong and Brown, Sandhurst Park, Tunbridge Wells, for a group of Orchids; Mr. Goodson, Fairlawn, Putney, S.W., for a group of Orchids; and Messrs. Sander and Sons, St. Albans, for a group of Orchids.

Silver Banksian Medals.—Messrs. Hassall and Co., Southgate, for a group of Orchids; Messrs. James Cypher and Son, Queen's Road, Cheltenham, for a group of Orchids; and Mr. R. G. Thwaites, Streatham, S.W., for a group of Orchids.

FLORAL COMMITTEE'S AWARDS.

Silver Flora Medal.—Messrs. Dobbie, Edinburgh, for Dahlias.

Silver Banksian Medals.—Mr. Ballard for Asters; and Messrs. Wells for Phloxes and Chrysanthemums.

Bronze Flora Medals.—Messrs. Stuart Low and Co. for Carnations; Mr. J. B. Riding for Dahlias; Messrs. Treseder for two Dahlia bouquets; The Wargrave Plant Farm for Asters; and Mr. J. Box for Lilliums.

The awards to Dahlias were made by a joint committee of the National Dahlia Society and the Royal Horticultural Society's floral committee.

WATFORD HORTICULTURAL SOCIETY.

THE fifty-seventh monthly meeting of the above society was held on the 12th inst. at the Church Road Schools, Mr. J. Stirton presiding. A paper on "Gathering and Storing of Fruit" was to have been given by Mr. G. Dyke, who wrote regretting his inability to attend. Mr. F. Newman, as he has done on previous occasions, kindly acted as deputy and gave the meeting some very useful and valuable hints on the subject, answering a number of questions at the completion of his paper. Mr. W. Hensley read a very interesting paper he had prepared on the subject of "Stove and Greenhouse Plants," and this was also followed by a discussion. Votes of thanks having been accorded to the lecturers and the chairman, the meeting concluded. A fine specimen of *Lilium sulphureum* was shown by Mr. W. R. Kettle.

EDITORIAL NOTICES.

Every department of horticulture is represented in **THE GARDEN**, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

*The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in **THE GARDEN** will alone be recognised as acceptance.*

NOTES OF THE WEEK.

An Effective Combination.—Anyone growing the beautiful Belladonna Lily can obtain a very charming effect by planting *Commelina celestis* with it, the beautiful sky blue flowers of the latter blending with the flowers of the Lily. These vary from white to a reddish or purplish hue, and the combination is very pleasing at this time of the year. Both are easily grown, providing they are planted at the base of a warm, south wall.

A Charming Perennial Sunflower.—A very beautiful plant is *Helianthus sparsifolia*, said to be a hybrid raised by crossing *H. rigidus* with *H. californicus*, a double variety. Certainly it is a grand acquisition, with large, deep yellow flowers from 5 inches to 6 inches across, which are carried upon long stems, thereby rendering it a fine subject for cutting and decorative purposes. It is a late-flowering kind, and produces a good display during September and October. It attains a height of 6 feet.

An Attractive Bed for the Autumn.—The Italian Starwort (*Aster Amellus*) is a very valuable plant for decorative purposes at this season of the year, either as cut flowers or in the garden, and a bed of it or any of its beautiful varieties, such as *bessarabiensis*, *Riverslea* and *littifolia*, intermixed with the beautiful Japanese Anemone Whirlwind or any of the other varieties gives a charming effect with very little trouble. Spanish Irises planted between the perennials would give a good display early next summer.

Our Special Rose Number.—As announced in our last issue, we shall publish next week a special enlarged number that will be of more than usual interest to lovers of Roses. Among the contributors will be such well-known experts as Miss Jekyll, Dr. O'Donnell Browne, H. R. Darlington, W. Easlea, F. Mawley, E. Molyneux, H. E. Molyneux and George Lang Paul. The half-tone illustrations will be of a unique character, and in addition there will be a coloured plate of two new Roses that have created quite a sensation this year. The price will, as usual, be one penny.

Beautiful Late-Flowering Clematises.—Although the majority of the Clematises are over, there are still one or two flowering that are of great decorative value. *Clematis joumana*, a beautiful hybrid between *C. Vitalba* and *C. davidiana*, is undoubtedly one of the best of them. The flowers, which are white, slightly tinged on the outside with lilac, are borne the full extent of the strong, vigorous shoots of this year, being very showy with the deep green leaves. This plant is often listed in this country under the name of *C. grata*. Then we have the free-flowering *C. Flammula*, the fragrant *Virgin's Bower*. This old but beautiful species is also of great value at this time of the year, with its sprays of fragrant, pure white, but rather small flowers, which are borne in great profusion. It is an elegant plant

for covering arbours, walls, or large tree stumps. Another sweet-scented species is *C. paniculata*, from Japan. It is very like *C. Flammula*, but the flowers are a little larger, and the leaves much coarser and more heart-shaped. All should be in a garden where autumn flowers are valued.

An Effective Bed for Next Year.—A very attractive bed for next summer can be obtained by mixing the graceful Iceland Poppy (*Papaver nudicaule*) with the beautiful Spanish Iris (*I. Niphium*). These can be purchased for a very small outlay, and should be planted now. The seedling Poppies which were sown a little time ago can be pricked out into the bed after the bulbs are in. If English Irises (*I. xiphoides*) are also mixed in the bed with the Spanish Irises, a longer display of blooms is obtained.

Are New Pentstemons Too Large?—In the course of a recent lecture given by Mr. Bernard Crisp on autumn border plants before the Royal Horticultural Society, the lecturer expressed the opinion that the large-flowered Pentstemon of to-day is less beautiful than the older type. We agree with Mr. Crisp that some of the alleged improvements of the Pentstemon are far too coarse and unwieldy. They are lacking in the delicate grace and outline we thought so beautiful in years gone by.

The Charm of Michaelmas Daisies.—On looking over the hardy plants in our garden last Sunday, after the absence of a week or so, we were rather abruptly reminded that winter is rapidly approaching, the Michaelmas Daisies, which are certain heralds, proclaiming the fact with a riotous profusion of flowers such as we do not remember seeing before. Even though they warn us of leaden skies and sodden soil, we must admit their charm. Early flowers of that giant lilac named *Chinax* are vying with the tiny white flowers of *Perfection*, while, near by, *Grey Dawn*, with tiny mist-coloured flowers, keeps company with the rose-coloured but larger *St. Egwin*. Truly they are a goodly host that the cultivator of hardy plants should make more use of.

A Plague of Caterpillars.—In many parts of the country there has been quite a plague of caterpillars on Cabbages and other members of the Brassica family this autumn, and many plants that were the pride of their owners a few weeks ago have been reduced to ribs as bare and gaunt as those of a weather-beaten hulk. The caterpillars are mostly those of the white Cabbage-butterfly, which lays its eggs usually on the under surface of the leaves. When these hatch, the young caterpillars develop a particularly voracious appetite and gorge until full grown, after which they make for the eaves of buildings or the under surface of railings, where they change into chrysalids, in which state they remain for the winter. Hand-picking and dropping the caterpillars into strong insecticide or neat petroleum is the only real remedy.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Pear Tree with Four Crops in One Season.—During the week ending September 20 I saw in a cottage garden at Bawtry, Yorks, a Pear tree which, so I was informed, has exhibited a characteristic probably unknown in the annals of British fruit-growing. For the last four years, the time the occupant had been in the cottage, I was assured the tree had borne three crops and attempted the fourth each season. On the day of my visit the tree had a moderate sprinkling of its third crop this season, while on about half-a-dozen or more growths were trusses just at their setting stage, the actual petals having been knocked off two days before by the heavy thunderstorm experienced over that district, which storm also brought down the first and second crops. I saw all the fruits, and there is a distinct difference in the stage of maturity between each lot of fruit. Those on the tree were about the size of a small Walnut, the second crop the size of a hen's egg, and the first lot about half as large again, or a little larger, and these were approaching a yellowish tinge of ripeness. The tree was a standard and perhaps some 20 feet high. Of course, neither of the following crops attains the size of the first, and are not of very good flavour. The name of the variety was not known. It might be added that the tree has not been pruned since the present owner has known it, also that the crop now setting never gets much further because of the advanced state of the season.—C. T.

A Beautiful Autumn-Flowering Shrub.—I have been much interested in the notes and articles on different plants and shrubs that flower in autumn which have appeared recently in THE GARDEN, and am therefore sending a photograph of what I consider to be the most beautiful of hardy autumn-flowering shrubs. This is *Tamarix Pallasii rosea*, or *T. hispida aestivalis* as listed by most nurserymen. The Kew authorities now, I believe, name it *T. pentandra*. But this confusion of names does not detract in the least from the charm and usefulness of the shrub. As will be seen, the young, erect shoots have the same feathery and graceful appearance as those of the ordinary Tamarisk, and in August these are surmounted by large plumes of rose pink flowers, resembling at a little distance those of *Spiraea* or *Astilbe Queen Alexandra*. The shrub illustrated is over five feet high, and at the time the photograph was taken created a great deal of interest. The flower-sprays are ideal for cutting. I believe at Kew the plants are pruned back almost to the ground-level each year, whereby flowering is delayed for a fortnight; but to get large bushes it is only necessary to cut away a little of the unripe wood in spring. Any good garden soil appears to suit this shrub.—E. G. G.

Saxifraga burseriana: Does It Need Sun or Shade?—The controversy over this question arose, I believe, through Mr. Farrer having recommended in one of his books that *Saxifraga burseriana* should be grown in shade. In one of his letters to THE GARDEN he asked me to bear him out in his statement that the Salurn Klamm is a sunless gorge, and that *S. burseriana* there grows in silt. I felt that it was unfortunate that I should be drawn into a controversy with a fellow-alpinist and be compelled to contradict him. I replied that as far as I remembered there was a considerable amount of sun in the gorge, and that the plant grew in scree rather than silt. If in this innocent pursuit of the truth my feet came heavily upon Mr. Farrer, it was the exact reverse of their intention, and I apologise for the blunder. Mr.

TAMARIX PALLASII ROSEA, A BEAUTIFUL HARDY SHRUB THAT FLOWERS IN AUGUST.

Farrer has since revisited the spot, and is now able "serenely to return to his original proposition" (see page 474). His original proposition was that it was a "sunless gorge." It now is that "after a certain amount of sun in the morning, the whole of Salurn Klamm is in the shade of its great walls for the rest of the day." This summer I also passed in the tram within half a mile of the Salurn Klamm, and saw the midday sun streaming into the mouth of the gorge. Not only was there a certain amount, but there was a considerable amount. Mr. Farrer has said that the soil in which *S. burseriana* grows in the Salurn Klamm is silt. He has even said this twice, and that because it is so. Why is it so? Because Mr. Farrer has said so—and repeated it? And he says that I must really revise my notions of

"scree." Scree is *débris* of rocks, shingle, loose stones. Silt is a deposit of mud or fine soil from running or standing water, fine earthy sediment. The material in which we found *S. burseriana* was *débris* from those very cliffs which failed to make the gorge entirely sunless, and its "coarseness of fine gravel" disqualified it as silt. I fully agree with Mr. Hornibrook and Mr. Farrer that it is vain pedantry trying exactly to copy natural circumstances under the altered conditions of the garden. In fact, I was surprised when Mr. Farrer instanced the alleged sunlessness of the Salurn Klamm to justify his recommendation of shade in the garden. He invited my corroboration, which I was unable to give. If he suffered under my tread, my anguish at the point of his pen has been no less acute. Our agonies being mutual, let us agree to court the lovely Gloria, each in his own way.—CLARENCE ELLIOTT, *Stevenage*.

—The conclusions of Mr. Farrer anent this fine alpine as given on page 474 interest and please me greatly, and I am in full accord with the idleness of "trying exactly to copy natural circumstances" for this or any other alpine. Indeed, the thing is impossible, seeing that should the cultivator be so clever as to closely imitate the soil and position in which this or any other alpine occurs, he still leaves behind the mountain with its altitude, its pure, rarefied air and the snow—at once a great coverlet in winter and a gigantic water supply in summer—none of which is possible of imitation. Hence, in a more or less slavish attempt to imitate soil and position, the cultivator would succeed in but minor degree at the utmost, and, were the other conditions essential, gardeners would be hopelessly handicapped at the outset. It was my realisation to the contrary that caused me some thirty or more years ago, when a great controversy raged in THE GARDEN concerning alpine plants and soils, to write of the indifference with which alpine plants regarded certain soils, an indifference only equalled by that for altitude and other things. Were it otherwise, the cultivation of alpine plants in lowland gardens would be an impossible thing. As it is, the mountain, the altitude and the snow would appear no more an essential to the successful cultivation of alpine vegetation than is the forest jungle to an epiphytal Orchid or Table Mountain to the "Flower of the Gods." Indeed, I believe I have in the past gone so far as to state that vegetable-life in Nature is very much a creature of circumstance planted by Dame Nature's hand, the plants doing their best to grow and increase after their kind, and presently becoming established there to the exclusion of all besides. In lowland gardens the conditions under which alpinics are cultivated are so entirely opposed to those of their native haunts that we can arrive at no other conclusion than that the latter mean but very little to the plants at all. In any case, so large a number so promptly adapt themselves

to their new environment that it might be interpreted thus with little fear of contradiction. And so with the unique Saxifrage, which has given rise to a controversy which cannot but be for good when all is said and done. Indeed, it cannot but be helpful to beginners when so good an authority as Mr. Farrer says that, given an adequate supply of moisture, he finds no difference, "either in health or floriferousness, between specimens grown in shade or in the fullest sun." I most cordially agree. Indeed, the whole of my experience is a complete endorsement of the statement, not only so far as concerns the subject of this note, but with many Primulas and such proverbially shade-loving plants as *Ranuncula* and *Haberlea*, which, given an adequate supply of water, are as perfectly happy in fullest sunlight as it is possible for plants to be. Such things are almost invariably planted in shade, however, because of our slavish imitation of each other's work. When, however, the cultivator has learnt the lesson that moisture within reach of the root-fibres is more than the equivalent of shade, he may then be tempted to bring supposed shade-loving subjects out into the open, there to provide a feature that was unknown before, and thereby also to add increased interest to some particular phase of gardening. A closing word as to soil. All the burseriana Saxifrages—and many others—have an abundance of fine threadlike, almost silken root-fibres. Root a batch of cuttings in June, and in August you will find root-fibres in plenty, 8 inches or so long, attached to a solitary rosette of half an inch high. Their numbers and their fine silken texture many years ago made me decide to give the plants a very sandy, finely-sifted soil, and the way the roots will ramify in such material is perhaps the best proof of its suitability to these plants.—E. H. JENKINS.

Artificial Manures and Vegetables.—This subject is of great interest, both to the exhibitor who requires size, quality and rapidity of growth, and to the commercial grower who must consider cost of production and subsequent market value. I cannot agree with "W. L." (page 471) that artificials have a detrimental effect on the quality, providing that a properly-balanced ration of potash, phosphates and nitrogen are used according to the requirements of the individual plant and the character of the soil. With regard to Celery, naturally a bog plant, my experience is that even on a heavy soil a fair amount of humus is necessary to retain moisture. Last year was undoubtedly a favourable period for Celery. For exhibition purposes I dug a trench as for Sweet Peas, 2 feet 6 inches deep, with a fair amount of animal manure incorporated, also a small portion of charcoal. The plants were put in the trenches on May 10, fed with equal parts of sulphate of ammonia and high-grade phosphate of potash. On August 4 the average weight was 10lb. a brace. The foliage was bright and of a leathery texture. The plant as a whole was exceptionally solid, and did not turn flabby even when left in the open for several days; the quality was grand. Occasional waterings with lime-water were also given to liberate the potash lying dormant. I also found that when Celery was grown with the usual amount of animal manure in conjunction with nitrate of soda only, the bulk was increased rapidly, with a corresponding decrease in quality, the growth being flabby and the plant drooping badly in the high temperature of the show tent. How frequently we see soapsuds being used in the Celery trenches! It is difficult to make an old gardener believe there

is no manna value there, the only advantage being derived from the water. The only alkali present in a hard soap is soda, often in the form of both caustic, carbonate and silicate, in conjunction with fatty acids and resin acids, which are a bugbear in the soil. As to the excessive use of artificials, I do think that certain vegetables will lose their keeping qualities, which I presume must be owing to the rapid growth and premature ripeness causing an early decay. I noticed Celery, especially white, also Onions, affected the most; but large Leeks were in good condition as late as April. Undoubtedly highly-concentrated chemicals in inexperienced hands are a positive source of danger; but to obtain size and quality, my choice is animal manure in conjunction with suitable artificials and plenty of lime.—FRED W. WAIR, *Lowdham, Notts.*

—In answer to "W. L." I can quite understand that Celery when grown with artificial manures (used indiscriminately) and without animal manures may be better in quality and, in fact, may be better in every respect than when grown entirely by the aid of animal manures. "W. L." writes freely about chemical and artificial manures (a vague term), but I find only two mentioned by name. Also, I can quite understand Onions and other crops being affected adversely as regards their keeping properties by the misuse of nitrates in any form; but when used judiciously in conjunction with other artificials I have never experienced any trouble in keeping crops. In agriculture, as "W. L." suggests, harmful effects have been experienced by many who have used nitrate of soda for hay crops; but I know that in many instances if the owner had known or had taken the trouble to find out beforehand the quantities of soluble and insoluble plant foods contained in the soil, and then to have endeavoured to have made up any deficiency by applying chemical manures, any harmful effects would have been avoided, for I have invariably found that where failure or injury, partial or otherwise, has followed the use of artificials, the fault has not been with the manures, but with the users. Nitrate of soda applied alone to any plant in liberal quantities would tend to overbalance the plant's energies into making gross and sappy leaf and stem growth, to the detriment of the health of that plant. Again, I should expect to find on any typical loam that indiscreet applications of nitrates in any form would injure the quality of Potatoes; but on soils deficient in nitrates, soluble or insoluble, the application of nitrates in a prudent manner could only tend to be beneficial. I admit that the ease with which they can be applied tends to make artificial manures dangerous in unskilled hands, yet the ease with which they are applied is one of the weightiest recommendations for their extended use; for whereas organic manures generally entail the expenditure of a large amount of labour and time, any chemical manure can be applied in a few minutes, and where labour is scarce and the saving of time in any department is an absolute necessity, this can only result in the general improvement of all parts. This is, I consider, a great incitement to the more extended use of artificial manures.—W. C. C.

FORTHCOMING EVENTS.

October 7.—Royal Horticultural Society's Exhibition at Vincent Square, Westminster. Scottish Horticultural Association's Meeting.

October 8.—East Anglian Horticultural Club's Meeting.

THE FLOWER GARDEN.

ANNUALS FOR FILLING FLOWER BORDERS.

WHEN flower-borders are newly arranged and the plants placed so as to be right when they have come to their strength, there will be gaps between for the first year. Some may like to crowd the border full at once, but the other way is the better one, allowing space for gradual root growth and securing the best form of grouping. This spacing offers an opportunity for a good use of annual plants. In order to preserve any scheme of colour that may be intended, the hardy annuals that are sown in September or March, and the half-hardy kinds that are put out in May or June, should be of the same colour as the permanent plants. The following lists give the names of some of the most useful and most easily grown, in separate colours, the words "back," "middle" and "front" indicating their place in the border.

White.—Back: Hollyhock, Poppy (double tall) *Nicotiana affinis*, *N. sylvestris*, *Impatiens Roylei*, variegated Maize. Middle: Sweet Sultan, China Aster Mammoth and any tall kinds, *Chrysanthemum coronarium*, *Polygonum Sutton's Gem*, Snapdragon (tall), *Godetia*. Front: Snapdragon Intermediate, *Clarkia*, *Gypsophila elegans*, *Jacobaea*, *Alyssum maritimum*.

Yellow.—Back: Hollyhock, primrose annual Sunflower, *Tropaeolum canariense*, Snapdragon (tall), *Oenothera lanarkiana*. Middle: Snapdragon Intermediate, primrose African Marigold, Sweet Sultan, *Gaillardia Double Yellow*. Front: Mignonette, dwarf *Tropaeolum*, French Marigold Miniature Lemon, African Marigold Dwarf Lemon, Feverfew Golden Feather, *Platystemon californicum*, *Limonanthus Douglasii*.

Orange.—Back: Annual Sunflower, French Marigold (tall), *Coreopsis Drummondii*, *C. tinctoria*. Middle: *Gaillardia picta*, *Calendula Orange King*, *Eschscholtzia californica*. Front: African Marigold (dwarf), French Marigold Dwarf and Miniature Orange, dwarf *Tropaeolum*.

Pink.—Back: Hollyhock, *Lavatera trimestris*, Snapdragon (tall), *Impatiens glandulifera*. Middle: *Godetia Double Rose*, Scabious, *Clarkia*, Snapdragon Intermediate. Front: *Phlox Drummondii*, *Hieraceum*, Indian Pink, Snapdragon (short).

Red.—Back: Hollyhock, tall Poppy, *Ricinus sanguineus*, *R. Gibsoni*, Snapdragon (tall), *Atriplex hortensis*. Middle: *Malope grandiflora*, Snapdragon Intermediate, *Linum grandiflorum*, *Alonsoa*. Front: *Phlox Drummondii*, dwarf *Tropaeolum*, *Collomia*, Snapdragon, Indian Pink.

Lilac and purple.—Back: Tall Poppy, *Salvia farinacea*, Scabious. Middle: China Asters (tall), *Ageratum mexicanum*. Front: *Collinsia bicolor*, *Ageratum* (dwarf).

Blue.—Back: *Convolvulus major*, Cornflower, Lupine (tall). Middle: *Nigella*, *Convolvulus minor*, *Lupinus Hartwegii*. Front: *Nemesia*, *Nemophila*, *Lobelia*, *Phacelia campanularia*.

It will be understood that in the case of annuals that are of many colours, such as China Asters, Snapdragons and *Tropaeolums*, the colour meant is that at the head of each list of plants of the three heights. Good cultivation is, of course, in every case essential, although this must not be taken to mean such heavy manuring as will tend to make the plants grow coarse. G. JERVELL.

BEST SWEET PEAS IN A SCOTTISH GARDEN.

WHILE at no time growing for exhibition, we still like to have good flowers for cutting and for garden adornment. We do not pretend to grow all the novelties, but rather content ourselves with a selection from the best of the older proved varieties, with an occasional new sort that takes our fancy at exhibitions. This has been our best season, for although buds dropped rather badly during June and early July, the plants were at the middle of September over ten feet high and covered with richly-coloured flowers of good size and with fairly long stems. "Fours" have been quite plentiful. It may now be of some little interest if I compare some of the varieties as grown here under identical conditions as to soil, manuring and exposure. If anything, Helen Grosvenor has been better than Edrom Beauty, although both are well worth a place in any garden. Maud Holmes has grown taller and flowered more abundantly than Dobbie's Sun-proof Crimson, but the latter gives more "fours." Early in the season Isobel Malcolm was better than Dobbie's Cream, but latterly the positions have been reversed. The former gave most "fours."

Barbara is much larger and a better grower than Stirling Stent, but not so deep in colour. Scarlet Emperor has been very fine indeed, and so has Red Star. The latter is the more brilliant in the bunch. Asta Ohn was better than Frank Dolby. I am sorry I missed Rosabelle this year when selecting, as I saw it very fine in Fife. John Ingman (Dobbie's stock) has been finer than ever before. Lady Miller is very beautiful and a shade deeper than Mrs. Routzahn. The latter has been very fine indeed. Norah Unwin has been the best white, both larger and purer than Etta Dyke. Nubian has outdistanced Othello, producing a large percentage of "fours." Mrs. H. Sykes has been much more floriferous than Elfrida Pearson, but the blooms are much smaller in size. The largest flowers were borne by Hercules. This is a magnificent Sweet Pea, the finest pink I have seen this season. W. P. Wright has been most disappointing. I was so taken with this last year that I purchased three packets of seed, and out of these obtained only about six plants true to name. Even these did but little good, the flowers being small and with a green tinge in them. Constance Oliver, Apple Blossom Spencer and the old Dorothy Eckford have been very good. I hope those who have to grow Sweet Peas under similar conditions to those experienced here will find the above particulars of some use.

C. BLAIR.

Preston House Gardens, Lullithgow

THE CAMPANULAS OR BELL-FLOWERS.

(Continued from page 473.)

C. haylodgensis.—This is a hybrid raised at Hay Lodge, Edinburgh, and is a charming plant, like the yellowish-leaved form of *C. Profusion* raised by Mr. E. H. Jenkins. It is of trailing growth, and has large, light blue flowers in June. Sometimes a little tender. Increased by division or cuttings.

C. hederacea.—This is really *Wahlenbergia hederacea*, and a lover of moisture, such as wet ditches. A charming native, raised by division

THE NEW PERPETUAL-FLOWERING CARNATION FAIRMOUNT (*Much reduced.*) (See page 500).

or from seeds. Blue flowers in July and August.

C. imeritiana.—About a foot high, with a spike of purple blue flowers in June. Apparently short-lived in gardens. Rockery, in light soil.

C. isophylla.—A charming, well-known basket or window plant, flowering in June, July and August, and often grown in gardens with grand effect, where it is hardy. Lovely on a wall in either the blue or white varieties, but suffering from wet in winter and requiring a sheet of glass overhead in many places. *C. floribunda* is apparently a form of this Bellflower.

C. laciniata.—About a foot high, this would be better appreciated were it not a biennial. It has rather handsome blue, open flowers in loose panicles in July. A hot, dry place suits this best. Division or seeds.

C. lanata.—I believe that this is the plant known as *C. velutina* at the present time, but *C. mollis* is said to be the same as *C. velutina*. It has been coming to the front lately, and it will probably do well if young plants are secured and planted in hot, sunny crevices, or in the moraine or wall garden. It has roundish, woolly leaves and graceful, light saffron blooms in July on arching stems. It is said to be a biennial, but this is doubtful. *C. l. alba* is very pretty.

C. langsdorffiana.—A synonym of *C. Parryi* and after the fashion of *C. rotundifolia*, with blue flowers in July. It is being offered as *C. Parryi* at the present time.

C. libanotica.—I only know this plant by sight, and am not prepared to say much about it. It ought, from its habits, to be hardy in dry rock gardens or in the moraine. It is a miniature *C. persicifolia*, about a foot high, and blooms in June and July.

C. longistyla.—Unfortunately, this is a biennial, but it has handsome blue flowers in good spikes in July, and with projecting styles, which add to its effect. Seeds. A dry soil in winter. About a foot high.

C. macrorrhiza.—A charming, rare species, with pretty tufts of leaves and lilac blue rotundifolia-like bells on slender branches in autumn. Capital for the rock garden, on large moraine, or wall garden. Seeds or cuttings.

C. Mayi.—A well-known basket plant and excellent for warm walls, especially where it can be shielded from rain in winter by a sheet of glass. One of the *C. isophylla* class, and raised by division or cuttings. July.

C. mirabilis.—A plant which excited a good deal of attention some years ago. It has large, blue bells on stout stems in August and September, is about a foot high, is only a biennial, and must be raised from seeds sown in May or June. A pleasing plant, but lessened in value by its biennial habit.

C. mollis.—There is a good deal of confusion about this plant. *C. mollis*, as I knew it years ago, was simply *C. portenschlagiana bavarica*, but the present-day plant is after the garganica fashion, with thickly wool-covered leaves and blue flowers, liking dry, sunny places. Division or cuttings. June and July.

C. muralis.—See *C. portenschlagiana*.

C. morettiana.—A plant after the fashion of a miniature *C. portenschlagiana*, liking cool, shady limestone rocks and difficult to establish. The flowers are lighter than those of *C. portenschlagiana*. Seeds, division, or cuttings. June and July.

C. nitida or planiflora.—A charming little miniature with erect stems 6 inches to 9 inches high,

and rather large, flat, open flowers in July. There are four forms, which are growing scarce. The type is single blue, alba is single white, and there are double forms of each. Grows on flat spots on the rockery or border, and likes some shade.

C. peltiformis.—See *C. carpatica*.—S. ARNOLD.
(To be continued.)

THE GREENHOUSE.

RAISING FUCHSIAS FROM SEED.

AS Fuchsias are so readily increased from cuttings, there is no reason to resort to sowing seeds for the propagation of any particular varieties, but at the same time the raising of Fuchsias from seeds is very interesting. As a raiser

of some of the varieties that are now in general cultivation, I have for many years paid great attention to the subject, and while meeting with some successes, have had many failures. Some of the Fuchsias, which if left alone will bear a great profusion of Cherry-like fruits, cannot be depended upon to produce a single fertile seed, while others whose fruits are of a more unpromising nature may be far more prolific in this respect.

I was first led to take up the raising of seedling Fuchsias by the late Mr. Thomas Todman, who a generation and more ago used to raise not only new Fuchsias, but Azaleas, Pelargoniums, Verbenas and other plants. He pointed out that, as far as his experience extended, having once found a good and reliable seed-bearer, it should be retained for the purpose, and indicated as one of the most useful plants he had a specimen bearing comparatively poor, semi-double flowers with a rosy white corolla. From this, though it was not worth keeping for its own intrinsic merit, he obtained many fine varieties by fertilising the flowers with the pollen of different kinds. Some of the progeny produced quite dark-coloured blossoms. I have endeavoured to find out whether the influence of the male or female parent exercises the greatest effect on the blossoms, but cannot say that I can settle anything to my own satisfaction.

At one time it was considered difficult to cross a variety having a white corolla with a dark one, but this proved with me one of the easiest of all, the progeny bearing corollas of different shades of pink or rose. In habit the seedlings varied considerably, the union of two vigorous-growing kinds often resulting in some comparative dwarfs, and *vice versa*. Among seedlings raised from ordinary green-leaved forms a bright golden-foliaged variety made its appearance, while from large-flowered kinds I raised almost a counterpart of the compact-growing, free-flowering variety Alice Hoffmann. One singular feature seems worthy of being recorded. A fertilised pod yielded only two good seeds, both of which germinated. In foliage, habit and flower the two plants resembled each other so closely that everyone would look upon them as identical, yet, strange to say, the cuttings from one of them took twice as long to strike as did cuttings from the other. Time after time the correctness of this was verified.

In order to save the seed we are sometimes recommended to rub the berries up with dry silver sand, but I prefer quite a different mode of procedure. When the berries are fully ripe, if they are then cut open it is quite easy to detect the fertile seeds, which may amount only to two or three, or even none at all. These can be readily picked off with the point of a penknife and transferred to a piece of blotting-paper; they will soon dry. Although this may appear a somewhat troublesome process, as a matter of fact it takes much less time than when the berries are squeezed to a pulp and mixed with sand.

The seed may be sown as soon as ripe, but I prefer to keep it till the end of February, when it is sown in some well-drained pots filled with a mixture of loam, leaf-mould and sand. These pots are then placed in a gentle heat of 50° to 65°, under which conditions the seeds will soon germi-

nate, when bright-coloured blossoms are appreciated more than at any other season. In the case of some species the flowers are borne in a terminal head or cluster. These are, as a rule, of upright growth, and it is useless to expect them to form bushy plants, as if the top is pinched out in order to encourage the production of side shoots, the plant does not readily break into growth, and, what is more, the weak shoots fail to flower in a satisfactory manner. As a rule, the winter-flowering members of this section, such as *J. chrysocephala* and *J. coccinea*, are seen at their best when grown in pots 5 inches to 6 inches in diameter and each carrying three good heads of blossoms. They may then be had well furnished with leaves, which is not the case if large specimens are aimed at. The propagation of all the Jacobinias is an easy matter, as cuttings of the young growing shoots taken as early in the spring as possible will strike root without difficulty if put into pots of sandy soil and placed in a frame where there is a gentle bottom-heat. They need to be shifted on into larger pots when required, and throughout the summer the best place for them is a frame where a fair amount of air can be given, shutting up the lights somewhat early in order to husband the sun-heat.

Of the Jacobinias that flower during the winter months, especial mention may be made of *J. chrysocephala*, a native of Mexico, which was first distributed about forty years ago under the name of *Cyrtanthera chrysocephala*. In this species the flowers are of a curved, tubular shape, and so disposed in a terminal head as to form a crown-like cluster. They are of a bright orange colour, and a group of this species in full bloom forms a very striking feature during a dull winter's day.

J. coccinea is in habit and cultural requirements much like the preceding, but the flowers are bright scarlet in colour. It is a native of Brazil.

J. ghiesbreghtiana was formerly known by the generic name of *Sericographis*. In this the deep scarlet flowers are produced in loose panicles, instead of crowded heads as in the two preceding species. The ovate-lanceolate leaves are quite smooth and of a very rich green tint.

J. pauciflora, under the name of *Libonia floribunda*, has been extensively grown for many years. It forms a freely-branched, bushy specimen, clothed with small, oblong leaves, and the flowers, which in a good example are exceedingly numerous, are

about an inch long, tubular in shape, and in colour scarlet, tipped with gold. It requires careful treatment, otherwise the leaves are apt to acquire a yellowish tinge, when much of the beauty of the plant is lost. In order to keep the leaves in good condition, an occasional dose of soot-water is very helpful when the pots are well furnished with roots.

J. penrhosiensis is reported to be a garden hybrid between *J. pauciflora* and *J. ghiesbreghtiana*, and the general appearance of the plant would suggest that such is its origin. It shows more of a leaning towards *J. pauciflora*, but the flowers have more crimson in their colouring, and the leaves, which are more pointed, are of a deeper shade of green.

Of the other species, *J. magnifica*, represented by several varieties, is a very striking plant, but its usual season of blooming is during the summer months.

H. P.

THE NEW PRIMULA VINEIFLORA SHOWN AT THE LAST MEETING OF THE ROYAL HORTICULTURAL SOCIETY (Two-thirds natural size). (See page 500).

nate, and with care the young plants grow away freely afterwards. Many of them will flower the first season, but it is only in the second year that one can form a reliable opinion of their merits. Seedlings raised from the pretty variegated-leaved variety Sunray have invariably come green, while the same results followed its use as a pollen-bearer.

WINTER-FLOWERING PLANTS FOR THE WARM GREENHOUSE.

THE JACOBINIAS.

SEVERAL of the plants now included in the genus *Jacobinia* have at one time or another been referred to other genera. Matters have, however, been simplified by bringing them all under one head. Some of them are particularly valuable from the fact that they flower during the winter

**OUR THIRD PRIZE
ROCK GARDEN.**

**DRYNHAM, OATLANDS
CHASE, WEYBRIDGE.**

THE gardens at Drynham were laid out some four or five years ago by Mr. William Barr, of Messrs. Barr and Sons, of Thames Ditton, and present many pleasing features of really natural gardening. The rock garden is a much more recent addition; in fact, a year ago it was not completed, it being purchased at the Royal International Exhibition of 1912, whence it was removed and reconstructed by Mr. J. Wood of Boston Spa. Naturally, on removing it to another site, the design had to be amended or altered to suit the new position, and considerable extensions were made along the banks of the already existing pond or pool, which, in the estimation of the designer and the owner, have added much to its beauty and effectiveness.

At the time of photographing, it could not be said to have attained its full beauty, as many of the more showy subjects were not in bloom, it being planted to provide, as far as possible, a continuous display as far as it is consistent with the natural scheme of construction. The first illustration shows the water inlet, where it falls with one or two breaks into a gourd, which again overflows into the larger but it flows in naturally over a shelving rock, ravine or gorge, thence into a pool in the fore-ground, seen in the third illustration. One or two

1. THE ROCK GARDEN AT DRYNHAM, WEYBRIDGE, SHOWING WATER INLET WITH *ARENARIA BALEARICA* AND OTHER PLANTS ON SHELIVING ROCKS.

2.—GENERAL VIEW OF THE ROCK GARDEN, WITH WATER FLOWING THROUGH GORGE INTO POOL BELOW.

of the most noticeable subjects are *Festuca glauca* (Blue Grass), *Tiarella cordifolia* (Foam Flower), Giant Thrift, *Arenaria balearica*, *Saxifragas* in variety (*S. Cotyledon* and *S. longifolius* just throwing up their flower-spikes), *Ranuncula pyrenaica* and *Sedum sarnmentosum*, *Convolvulus Cneorum*, though not quite hardy, had come through the winter well and was showing flower, while *Veronica repens*, planted almost on the water level, was a mass of white blossoms. The second illustration is a more comprehensive view of the rockery, as it really includes the first illustration, but it gives a slight idea of the gorge or ravine with the stream running into the pool in the foreground and the shelving rocks on either side. These are planted with an infinite variety of small and interesting subjects, *Sempervivums* and *Sedums* in variety are installed with many of the first-mentioned plants in niches on either side of the ravine, while on the more exposed parts of the rockery are four patches or groups of *Lithospermum prostratum*, *Hebevillea grandiflora*, *Theris gibraltarica*, and *Helianthemum* in variety, *Lychnachia aurea* (yellow Jenny Creeper) showing up well against the intense blue of the *Lithospermum*, *Primula sikkmensis* and *P. corkburniana* were flowering well, as also was *Gnaphalium*

Leucopodium, this growing in fine masses and being covered with bloom.

On the moraine or right-hand side of the illustration are many minute and interesting subjects, such as *Encarnated Saxifragas*, *Lachnium alpina*, *Potentilla pyrenaica*, *Dionaea epipactis*, *Saxumaria canadensis*, *Soldanella montana*, *S. alpina*, *Ranunculus crenatus*, *R. amplexicaulis* and *R. bilobus*, *Salix pyrenaica*, *Bellis carulescens*, and *Cardamine trifoliata*.

The third illustration, looking east, is a continuation of the rockery running down to and by the side of the pool. Here some of the larger masses of the stone are already getting well covered with *Saxifragas*, *Thymus*, *Erodiums*, &c., while *Primula japonica*, *Spiraeas*, *Iris* and other moisture-loving subjects are planted by the water-side. On the banks extending beyond and backing up the rockery are planted such subjects as shrubby *Veronicas*, *Cytisuses* in variety, *Rosa rugosa*, *Weigela*, *Abutilon vitifolium*, *Lupinus*, &c., the pool itself being planted with various aquatics, including a good collection of *Nymphaeas*.

TREES AND SHRUBS

LATE-FLOWERING SHRUBS FOR SHADED PLACES.

THE SHRUBBY ST. JOHN'S WORIS.

THE shrubby species of *Hypericum* or St. John's Wort form an important group, for they blossom during summer and early autumn, a time when flowering shrubs are becoming scarce; and some of them are well adapted for planting in semi-shade, for they thrive even when planted close up to the trunks of large trees, such as Limes and Oaks. One point may be urged against them, viz., the lack of variety in the colour of the flowers, for all are yellow, though there is some difference in shade. There is, however, considerable variation in the size of the blooms and the manner in which they are produced, while a wide difference exists between the habit and stature of the various species.

Propagation.—Taken as a whole, their cultivation offers no difficulty, for, providing moderately good loamy soil is given, they grow and flower freely, while a few give quite good results when planted in sandy ground. It is a mistake to keep the plants too long, however, and as soon as signs of deterioration appear they should be destroyed and a fresh start made with young stock. Young plants are easily raised, for seeds collected in autumn and sown in sandy soil indoors during early spring vegetate quickly, and nice plants are produced in the course of the succeeding summer. Many of the kinds may also be increased by means of cuttings of half-ripe wood inserted in pots of sandy soil in a close frame in July, and such species as *H. calycinum* are easily increased by division in spring.

Pruning.—One point to be observed in the cultivation of these plants is the necessity for an annual pruning during late winter or early spring. February is a very good time for the work, and it should consist of cutting last year's shoots back

quite halfway and removing many of the weaker branches right to the base. In the case of *H. calycinum* the plants may be cut over to the ground-line, and in this instance the work may be reserved for March. The strongest growing kinds are benefited by a surface dressing of well-decayed manure in March or April every second year, especially if the soil is not very good. They do not often suffer seriously from drought, although, as is the case with other shrubs, they appreciate a good watering now and then in very dry weather. Of the many kinds which may be obtained, a selection is appended of those which are suitable for general planting.

H. androsamum is a European species which is known under the common name of Tutsan. It grows from 1½ feet to 2 feet high, and forms a shapely, wide-spreading bush with broadly ovate or almost elliptical leaves and large heads of small

found wild in the British Isles where it grows from 12 inches to 15 inches high, bearing rich golden flowers ½ inches or more across.

H. densiflorum, *H. kalmianum*, *H. glaberrimum* and *H. prostratum* are North American species which grow about two feet high, forming rather dense bushes made up of numerous twiggy branches clothed with small, narrow leaves, and bearing pretty golden flowers in large heads. The botanical differences which separate the species are small, and there is little to choose between them for beauty.

H. elatum is a vigorous-growing plant from the Canary Islands. Attaining a height of from 3 feet to 4 feet, it blossoms freely when planted in full sun, but when planted in shady places it often fails to do itself justice.

H. hookerianum is one of the best of the taller-growing kinds. It is a native of the Himalayas,

3.—CONTINUATION OF THE ROCK GARDEN BY MARGIN OF THE POOL.

yellow flowers, which are succeeded by showy black fruits.

H. ægyptiacum, *H. balearicum* and *H. olympicum* are three dwarf showy species from the Mediterranean region and Asia Minor which are suitable for the rockery. As they are inclined to be tender, they should be given a sheltered but sunny position. The last named is specially worthy of note, for it is very floriferous, and the flowers are large and showy.

H. aureum, a native of the Southern United States, grows 2 feet or so high and blossoms freely; while *H. Buckleyi*, a dwarf-growing kind from the mountains of the same country, should find a place on the rockery.

H. calycinum is perhaps the most useful of all the *Hypericums*, for it succeeds in sun and shade, and is an excellent plant for carpeting ground beneath trees. A native of the Orient, it is also

and grows from 2 feet to 2½ feet high. The oval leaves are somewhat glaucous in colour, and the shapely golden flowers are upwards of 2 inches across.

H. patulum, a native of India and China, is an elegant little bush, bearing large golden flowers, but it is rather tender and delicate, and for general usefulness has to give place to its more vigorous variety *Henryi*. This grows into a good-sized spreading bush, and bears its large golden blossoms freely.

H. moserianum is a charming hybrid between *calycinum* and *patulum*, and it inherits the good qualities of both, while it is much harder than *H. patulum*. It grows about a foot high, spreads freely into a plant 1½ feet or 2 feet across, and blossoms with remarkable freedom, the flowers being large and of a rich golden hue. It is an excellent subject for specimen beds or groups in the front of a shrubbery.

W. D.

THE ROSE GARDEN.

SIMULTANEOUS SPORTS AMONG ROSES.

THERE have been quite a number of instances where a certain variety of Rose has sported in exactly the same way on different plants in widely-separated districts. Doubtless this has been the cause of some duplicates or synonyms, and it becomes almost necessary to enquire if others have the same sport before distributing your own to the public, and so having the same variety under more than one name. A few examples of this occur to me, but we also have the same fact among Chrysanthemums, Pelargoniums and other florists' flowers that are largely propagated by cuttings or grafts. I think it was in the year 1892 that the Rev. G. H. Engleheart explained his

older plants simultaneously to its discovery at Reigate. Dorothy Perkins has produced quite a number of sports remarkably alike, and all the more so if we take into consideration how variable the sports themselves are. I have frequently found a stray flower or two of the true Dorothy Perkins in the midst of White Dorothy, and also in those beautiful bluish pink trusses of Dorothy Demmon and Christian Curle. Lately there has been considerable discussion re the number of duplicates, which are all too frequent; but those emanating from sports may often have been genuine and distributed with all honesty as being distinct, so far as the raiser was aware. A. P.

NEW AND RARE PLANTS.

AWARDS OF MERIT.

Primula vincællora.—This remarkable species (see illustration on p. 497) was sent by Professor Bayley

Carnation Fairmount.—This is a grand perpetual-flowering variety, after the colour of Mikado (bluish blue), but an improvement in many ways. In colour it is almost fascinating, while the flowers are large, full and fragrant. Shown by Messrs. Allwood Brothers.

Chrysanthemum Olive. A fine, early-flowering border variety of chestnut crimson colour and bronze reverse. From Messrs. W. Wells and Co.

Rose Moonlight.—This variety recently received the gold medal of the National Rose Society. It was shown in lovely form in large trusses of expanded flowers. Shown by the Rev. J. H. Pemberton.

Aster Beauty of Ronsdorf.—This in time will prove a very popular variety. It is a form of Aster Amellus, with blooms measuring 3 inches in diameter. It is heliotrope in colour and less than two feet in height.

Aster Mrs. Frank Penn.—This is a variety of A. Novi-Belgii. Its attraction lies in its wonderful colour, which is bright rosy purple. Shown by Messrs. H. J. Jones, Limited.

NEW DAHLIAS.

Awards of merit were given to the following by a joint committee of the National Dahlia Society and the floral committee: Rupert, from Mr. Shoemith, Woking; Homere, from Messrs. J. Burrell and Co.; Dorothy Hawes, from Messrs. Stredwick and Son, St. Leonards-on-Sea; Reginald Cory and Ruly, from Messrs. Cheal, Crawley; Mrs. J. C. Vaughan and Herzogin von Braunschweig, from Messrs. Warnar and Co., Holland.

NEW ORCHIDS.

Lælio-Cattleya Armada.—This is a distinct hybrid from L.-C. luminium and C. fulvescens. It has yellowish sepals and petals, and purplish crimson lip. Exhibited by Sir G. Holtford.

Cattleya Cybele Davidson's Variety.—A fine Cattleya derived from the intercrossing of C. gaskelliana alba and C. luddemaniana. The sepals and petals are almost white, and the lip has a yellow throat, then a purplish crimson area, nicely margined with white. From E. H. Davidson, Esq., Orchid Dene, Twyford.

The foregoing were shown before the Royal Horticultural Society on September 23, when the awards were made.

NEW FRUIT.

Damson Merryweather.—It is seldom that a new Damson is put before the fruit committee. This variety, however, is of such surpassing quality that it was unanimously given the high award of a first-class certificate. A coloured plate of this variety appeared in THE GARDEN, October 22, 1911. The trees of this Damson are as vigorous as a Victoria Plum, and the fruits much larger than the largest Damson hitherto known. It has a fine Damson flavour, and even in the young state the trees crop heavily. Shown by Messrs. Merryweather and Sons. This variety was shown at the Royal Horticultural Society's Fruit Show on September 25.

A BEAUTIFUL WATER-SIDE GROUPING OF THE ALKANET, ANCHUSA ITALICA DROPMORE VARIETY. HOW TO INCREASE THIS PLANT IS FULLY DESCRIBED ON THE OPPOSITE PAGE.

theory of the matter to me, and it was very striking. That gentleman's explanation was that a special variety so propagated was really one and the same plant as if they—or the piece of growth removed—were upon the original, and that upon arriving at a certain stage or age they all developed the same peculiarity. He gave a further illustration by saying that where a disease or singularity of mind or body was inherent in a family, it commonly appeared among the members at precisely the same time of life.

I have known of several instances of what were undoubtedly simultaneous sports. There are the cases of Mrs. Harkness and Paul's Early Blush sporting from Heinrich Schulthers, also Souvenir de S. A. Prince and The Queen from Souvenir d'Ami. The same variety threw a white sport near here at the same time, as nearly as I can discover. The sport from Catherine Mermet—Muriel Graham—also appeared upon one of our

Balfour from the Botanic Garden, Edinburgh, where it has this year flowered for the first time. The flat, expanded flower is pale violet in colour, deepening in shade in the centre of the flower. It was collected by Forrest in 1905 in the Lichiang Mountains of Yunnan, and introduced through Messrs. Bees, Limited.

Berberis aggregata.—This new Chinese species was shown by the Hon. Vicary Gibbs (gardener, Mr. E. Beckett). It is one of many ornamental shrubs sent home by Wilson from China. It was shown as a richly-berried shrub of spreading habit less than two feet in height. The berries are of a creamy hue, rosy on the sunny side, and produced in immense clusters.

Carnation Salmon King.—An effective and beautiful variety with bright salmon rose flowers. It is perpetual-flowering, fragrant and very free. Shown by the raisers, Messrs. Stuart Low and Co.

GARDENING FOR BEGINNERS.

THE CULTIVATION OF THE DROPMORE ALKANET (*ANCHUSA ITALICA* DROPMORE VARIETY).

EVERYONE with a fairly wide flower border should grow the delightful blue-flowered Dropmore Anchusa. It rivals the Delphinium as the best tall-growing blue-flowered perennial. Were the plants only in flower for a fortnight or three weeks, this Alkanet would be worth growing; but as a succession of flowers is maintained for something like three, or even four months, it is of inestimable value for borders and beds. Commencing to flower towards the end of May when about two feet high, the plants in good soil will grow 6 feet or more in height, producing a profusion of blossoms throughout the summer. If the shoots which have flowered are cut out in August, side growths will push up and flower in autumn. Unlike many tall herbaceous plants which produce flowers only near the bottom of the growths, the Dropmore Anchusa has flowers practically from the bottom to the top when not crowded with other plants. (See illustration on opposite page).

Root Cuttings form the readiest means of propagation. At this season of the year one or two plants may be lifted to obtain a supply of the thick, fleshy roots. These should be cut into pieces 2 inches to 3 inches; some may be thicker than one's thumb, while others will not be thicker than, or even as thick as, a pencil. Under favourable conditions almost every piece of root will produce a young plant. It is important when cutting up the roots to have the cut surface at the top straight across and the bottom slanting; otherwise, when planting the pieces of root which are the same thickness all the way along, it will be difficult to decide which is the bottom and which the top. For safety, especially when the garden soil is heavy, some growers lay the roots 2 inches apart in boxes of very sandy soil for the winter. Placed in a cold frame, these will start into growth in early spring, and should then, during favourable weather, be planted out where they are to flower. Another method is to lay the roots in soil at the foot of a warm south wall for the winter, planting them out as before recommended in early spring.

Though a hardy perennial, in heavy, wet soils the Anchusa roots often rot off in winter. In such gardens a supply of roots should be obtained from the old plants which have flowered, and placed in a cold

frame annually in autumn. As a contrast to this, in light, sandy soils, when the border has been dug over, pieces of the root will grow and push up all over the surface of the ground. The old

who do not already grow the Dropmore Alkanet, and anyone interested in obtaining variation in colour, may sow seeds under glass in a heated greenhouse during February, or in a cold frame from April to June. The paler variety named Opal, which is grown in some gardens, was obtained in this way.

To aid in securing the succession of flowers which is such a desirable feature of this beautiful blue-flowered perennial, the plants should be liberally mulched with old decayed manure towards the end of May. Staking the leading shoots is desirable during June; otherwise, later in the season the growths will fall about and tying will then be much more difficult. Cut sprays are useful for room decoration, being particularly effective with a few pieces of *Gypsophila* interspersed.

PRUNING GOOSEBERRIES AND RED CURRANTS.

In districts where birds are not troublesome, the early pruning of Gooseberries and Currants is advisable. A number of years ago I pruned a Gooseberry bush in a large plantation, just one bush, at an early date, leaving the remainder to be pruned the following spring. The new shoots on the autumn-pruned bush grew very strongly and early, and, of course, the berries were large.

If the Gooseberries are intended for exhibition, the pruning of the branches must be rather more severe than in instances where the crop is intended solely for home consumption. In the first case leave the branches quite 6 inches apart; prune the side shoots back to two buds from the base if these branches grow from spurs, and to three buds if they grow from main stems. The leading shoots must be cut back to half their length. The same system may be applied when pruning Red and White Currants.

If pruning be done to form bushes for bearing general crops of fruits, then the main branches should be left about four inches apart; but the side shoots must be cut back as advised in the case of pruning for exhibition fruit. The leading shoots, however, need not be cut back more than one-third their length. I refer, of course, to shoots made during the current year. Always prune to a bud pointing outwards and upwards; then the new shoots, especially the leading ones, grow in an upward direction, and so improve the form of the bush and keep the branches from being weighed down by the quantity of fruit.

ROOT CUTTINGS OF THE DROPMORE ALKANET READY FOR PLACING IN A COLD FRAME FOR THE WINTER.

ROOTED CUTTINGS, SHOWING HOW THE NEW GROWTHS ARE PRODUCED. THESE QUICKLY MAKE LARGE PLANTS.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Rose Garden.

Planting Fresh Beds.—Readers who intend planting fresh beds this season would be well advised to get the ground or beds prepared as early as possible, as early planting, I feel assured, is a great factor towards the ultimate success of the plants.

Preparation of the Soil.—Early deep trenching and plenty of manure well below the surface are quite essential, with a sprinkling of bone-meal in the top spit, while the addition of some clay or very heavy loam to the lighter soils is a distinct advantage. But with present-day varieties the necessity of heavy soil to ensure success is not so marked, as even on very light soils, well manured, excellent results can be obtained.

The Flower Garden.

Stock Plants of tender subjects should be lifted as soon as there is danger from frost, and after potting should be well watered in. Though it may not be necessary to place them in the houses at once, they should be placed in the frames or under a temporary shelter, removing them to the houses as soon as the more particular occupants have been allotted their various positions for the winter.

Clearing the Beds.—Presuming that the weather conditions are such that it is not advisable to leave the occupants of the beds out any longer, a commencement should be made to clear them, and, where spring bedding is practised, the sooner the better, as bulbs and other plants employed do all the better if they are planted fairly early. This double planting (for a spring and a summer show) takes a great deal out of the soil, and I find it best to manure in the autumn rather than the spring.

Plants Under Glass.

Salvia splendens.—This slowy subject should be housed at once, giving the plants as much room as possible between them, or they are apt to draw up rather quickly. The latest batch which may have had the points of the shoots removed recently might still be left out under a temporary shelter, but as they are easily damaged by frost, no undue risks should be taken. Plenty of water will be required after housing, and one or two feedings of artificial manure will, or should, ensure good flower-spikes.

Zonal Pelargoniums.—If not already housed, these should be put inside at once. Shelves or stages near the glass are the best places for these plants. The foliage this season is fairly hard or ripe, and it may be advisable to spray between the pots for a few days after housing, or a loss of foliage may result from the drier atmospheric conditions. All the light and air possible should be given these plants, giving no fire-heat till frosts or extra cold weather makes it a necessity, or until the presence of the bloom makes it necessary to maintain a drier atmosphere.

Azalea indica.—Those plants that may have been removed outside to mature their wood should be placed under cover again, giving the plants a spraying with an insecticide to ensure they are free of thrip. Careful watering is necessary during the winter, and though they do not like an excess of water, if once they become dry it will possibly result in a great loss of foliage.

Primulas that may have been growing in cold frames should be removed to pits or houses where a little heat may be turned on during bad weather or cold nights. The species *P. malacoides* may still be kept in a cold frame providing the weather keeps dry, but too moist an atmosphere often causes damping of the foliage, especially in large plants.

The Kitchen Garden.

Late Potatoes that may still be in the ground should be lifted at once, choosing a dry day for the operation. Leave the tubers to dry as long as possible before storing. Where shed-room is available, they are best stored under cover, where they can be picked over during bad weather. Failing this, they should be pitted in as dry a position as possible. In this latter case they must be very carefully picked over in case of disease, as they often rot wholesale if pitted without very careful attention in this respect.

Spring Cabbage.—This is a very important crop, and planting should be done at once, selecting a piece of ground that has been well manured for a previous crop. Light soil should be made fairly firm before planting, or the soft growth made on such soil may easily be damaged by frost later in the season. The very early varieties need not be planted too far apart, but rather more space should be allowed for the later varieties.

Hardy Fruit.

Root-Pruning.—As the bulk of the fruit is gathered, attention should be paid to those trees that are not fruiting satisfactorily, owing probably to over-rampant growth. It is not of much use pruning such trees, as the more one prunes, the more rampant is the growth the following year; hence the necessity for root-pruning.

Large Trees should be taken in hand first; and though one often sees it advised to do one side or half round the tree one season and the other half the next, I do not believe in it. I would rather sacrifice a crop for one year if it is to ultimately result in good crops of fruit. The only reason for doing it is because the tree is not making sufficient fruiting wood, so there is very little sacrifice, if any. By doing this early and by getting well round and under the trees, afterwards placing some good soil in close proximity to the pruned roots and preserving as many of the young fibrous roots as possible, the trees have a chance of making quite a lot of young roots before the depth of winter, and so very little check results except that less growth is made the following season, which is the one object aimed at. Such large trees sometimes need attention as regards watering and mulching if a dry spring follows the pruning, but otherwise I have always found them to come through all right.

Smaller Trees and Cordons are very easily manipulated, and in the case of the latter, young, fast-growing trees should be taken out and replanted every two or three years, and if this is done it will be found that the roots are almost as much under control as those of pot trees.

THOMAS STEVENSON.

(Head-gardener to E. Mocatta, Esq.)

Woburn Place Gardens, Adlestone, Surrey.

FOR NORTHERN GARDENS.

The Flower Garden.

Planting Bulbs.—It is rather early yet to remove bedding plants and commence what is popularly known as spring bedding; but wherever bulbs are to be planted elsewhere, they should be got in as soon as convenient. Cottage Tulips, Darwin Tulips, and Spanish and English Irises should all find a place in considerable quantity. These should all be planted about three inches deep, and they may all be planted at from 6 inches to 9 inches apart. Where the soil is at all heavy, it is worth while placing a trowelful of clean sand round the bulbs of dear varieties.

Note-Taking.—Before the impressions of the closing season fade from the memory, notes should be taken of successes and failures, both as regards varieties and their arrangement; and however much it may eventually be modified, a draft arrangement for next season should be made. In the herbaceous quarters, too, plants to be subsequently discarded or shifted should be marked.

Protecting Dahlias.—In certain localities early frosts, succeeded by a spell of mild weather, often occur and destroy the Dahlias. If a piece of scrim or other light material were thrown over them when frost occurred, the blooming period might be prolonged for several weeks yet.

Late Carnation Layers.—These should now be severed from the parent plants and placed in their winter quarters. If afforded the shelter of a light to ward off soaking rains, it will be a great advantage. I favour potting them up, but if this is not done, they should have some nice fibrous loam to root into. This will tell at planting-time.

The Rock Garden.

Autumn Planting.—Any autumn planting should no longer be delayed. Evaporation is slow now, and there is just time for the plants to get rooted before winter sets in.

Preparations for Building.—Where it is intended either to extend the rock garden or to form a new one, preparations must be made beforehand. The procuring of stones is the first consideration, and in dealing with this aspect of the work the welfare of the plants should have precedence to mere spectacular effect. Sandstone and limestone will be found to be generally most suitable, but sometimes one must build with the stones they have. I recently utilised some disused concrete, thickly studded with small stones, with good effect. Soil is the next consideration, and medium loam will suit the bulk of the plants, but peat and rotten rock are also necessary where a varied collection is to be grown.

Plants Under Glass.

Chrysanthemums.—Feeding must still go on, being required more than ever now. Disbudding must also be carried on as the buds are fit for handling, that is, when they are about the size of Peas. Any late varieties which have not set their buds should not be housed till they do so, or they will most likely "go blind." Should sharp frost occur, lay the plants on their sides overnight. They will stand several degrees of frost in that position.

Salvia Heeri.—Those who possess a batch of this attractive spring-flowering scarlet *Salvia* should give it a light, airy position in the greenhouse and continue to give it liquid manure twice a week throughout the winter.

Bulbs for Forcing.—Batches of these should be potted or boxed up, after which they should be plunged in sand or ashes in a sheltered corner.

Shrubs for Forcing.—As soon as they come to hand, these should be potted up and placed in a cool structure. Place them in as small pots as possible.

Fruits Under Glass.

Strawberries.—Some growers lay the pots on their sides at this season to protect the plants from heavy rains, while others house them in cool structures. Those, however, who have experimented in the matter have found that, other things being equal, the best results have been obtained from plants which have been plunged in the open air in an upright position, and covered with lights only during heavy rains.

Bottling Grapes.—This has no reference to the modern system of bottling fruit by the sterilising process. Where the house is wanted for plants, the bunches can be cut with a piece of the branch attached. This piece of branch should then be inserted into the mouth of a bottle of water, a nodule of charcoal having been placed in the water, and the bottle adjusted on a shelf in a dry, cool room at an angle so that the fruit will hang clear.

The Hardy Fruit Garden.

Root-Pruning.—This work, which was referred to some weeks ago, should now be completed without delay, so that young, fibrous roots may be formed before winter sets in.

Purchasing.—Those about to plant will now be selecting varieties—a very important step. Growers of experience need no advice, and beginners would do well to consult successful growers in their own locality, as so much depends upon soil and situation. For cooking Apples, however, one cannot go far wrong with such varieties as Early Rivers, Ecklinville, Lord Derby, Stirling Castle, Warner's King, Bramley's Seedling and Lane's Prince Albert. For dessert purposes the following are very reliable: James Grieve, Worcester Pearmain, Allington Pippin and Cox's Orange Pippin.

The Vegetable Garden.

Asparagus.—See that the beds are thoroughly cleared of weeds, but do not cut over the plants till they die down.

Brussels Sprouts.—Remove all decayed and decaying leaves, so that the sprouts may enjoy all the available air and light. Endeavour to utilise the sprouts before they lose their solidity, which the more precocious ones often do rather quickly.

Clearing Off Crops.—All summer crops should be cleared away as soon as they are harvested.

Late Cauliflowers.—Varieties like Veitch's Autumn Giant and Sutton's Mammoth will be proving useful. As they develop, break the leaves over the curd to preserve its whiteness and to protect it from frost.

CHARLES COMFORT.

Broomfield Gardens, Davidson's Mains, Midlothian.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—*The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.*

FLOWER GARDEN.

NARCISSUS FLY (C. M. D.).—The grubs attacking the Narcissus are those of the Narcissus Fly (*Merodon equestris*). You will find a good deal of interesting and valuable information about this worst pest of the Narcissus in some of our recent issues. If you can dig up and examine the bulbs immediately, that will be the best measure to pursue, destroying all those affected. The fly appears in May, and may be caught in the manner described in the articles referred to. You should notify the occurrence of the pest to the Board of Agriculture, Whitehall, S.W., as this is one of the scheduled pests, and failure to notify renders one liable to a penalty.

TWELVE SWEET PEAS FOR EXHIBITION (F. C.).—It is really a difficult matter to give the names of the best twelve varieties of Sweet Peas, as these vary in different localities and under varying weather conditions, but the following list should supply your needs: Margaret Atlee, Thomas Stevenson, King Edward Spencer, Walter P. Wright, R. F. Felton, King Manoel, Edrom Beauty, Elsie Herbert, Evelyn Homus, John Inman, Elfrida Pearson and Herules. Others almost equally good are Mrs. Cuthbertson, Sealoe Emperor, Princess Mary, Mrs. Harcourt Sykes, F. H. Taylor, Queen of Norway, Prince George, Florence Wright Spencer, Rosabelle, Barbara, Clara Curti and Lavender George Herbert. Edrom Beauty and Barbara need shading to exhibit in the best condition.

VIOLAS AND DAFFODILS IN ROSE-BED (Bedder).—You may plant Violas beneath your bush and standard Roses for the summer months, but it is advisable to remove them in the autumn, in order that the soil may be rested during the winter. When a surface plant is used in this way, care must be taken to add new soil or manure to the beds during the winter, in order that the soil shall not be unduly impoverished. We do not advocate planting Daffodils in Rose-beds. They are deep-rooting and rank-fewer subjects, and impoverish the ground to some considerable extent. In the event of bulbous plants being required, Snowdrops or Chionodoxas should be chosen; but if Violas are to be used in the summer, it would be better to confine your efforts to them. If too much is attempted, the Roses will be sure to suffer in the end.

SCENTED STOCKS (H. D.).—These sweet and popular flowers may be divided into two types, winter and summer. The former should be sown in late July, and planted out in autumn to flower in the following summer. These go by the name of Brompton or Intermediate Stocks, and sometimes East Lothian. The other type is the summer stock, commonly called the Ten-week Stock, meaning that it will flower within this time from the date of sowing the seed. The seed of this should be sown early in April in a frame on a fermented hot-bed with very slight heat, transplanting as soon as large enough to handle into a cold frame in light soil, 4 inches apart. Plant in their summer-flowering quarters about the middle of May. If you have not the convenience for sowing the seeds, you can buy the plants of the colours you prefer by advertising in THE GARDEN.

PLANTS FOR SOUTH BORDER (Rosa).—Of the subjects you have hitherto tried for the border, the Phloxes and Gladioli were the least likely to give good results, the former being of a moisture-loving nature, the latter also requiring rather generous treatment. Even the specimen Lilies would have been happier in some shady spot; hence the selection was rather at fault. You might, however, try *Lilium candidum*, the well-known Madonna Lily, which delights in a warm position. As it is so cheap and good, you might plant it throughout the whole length of the border near the base of the wall and in unmanured ground. It is a good time to plant it, and if you secure the best bulbs, a flowering would be assured in the coming year. Other Lilies not averse to sun and warmth are *testaceum*, *croceum* and the sturdy forms of *umbellatum*, any of or all of which could be planted freely in clumps of a dozen or more. For spring effect you might plant some of the more plentiful of the Daffodils, as Emperor, Golden Spur, Sir Watkin, Empress and ornatus, and, to follow these, masses or groups of Spanish Irises, which are very cheap by the hundred or thousand.

These would carry you into July, and if the border were well dug and manured, save for the Madonna Lilies first mentioned, you might add hybrid Columbines, Delphiniums, Galliarthas, Helianthus of sorts, Aster Anellus in variety, *A. acris*, *Sedum spectabile atropurpureum* and other flowering plants that would continue the display well into the autumn months. You might also invest in "The Hardy Flower Book" (Jenkins), which gives selections of plants for many positions. Such a book would afford you much reliable information. It may be had from these offices, post free, for 2s. 10d.

DESMODIUM AND GUNNERA (J. W. M.).—The *Desmodium* provided the plant is not too large or old—might be moved at any time within the next few weeks, or be left until spring. Youthful specimens are not difficult to re-establish, though older ones take less kindly to the soil because of a sparsity of root-fibres. If you have no special desire for disturbing the *Gunnera*, it might be deeply mulched in its present position. There is no need for disturbing the undug ground, as the roots will quickly ramify into the new soil and afford support to the plant. The mulching could be done without in the least damaging the roots of the plant, whereas to dig among them would cause much mutilation. In your district lifting and dividing might be done at once, while in colder parts of the country these operations are best deferred till spring. As the plant appears to be doing uncommonly well, it is advisable, we think, to let well alone.

TREES AND SHRUBS.

CLEMATIS FOR NAME AND TREATMENT (J. D.).—The specimen No. 9 sent for name is *Clematis Viticella*. The growths made this year should be cut hard back in February. Just how hard back will depend on whether you wish the plant to increase in size and cover more space, in which case you need only cut back the young growths to hard, firm stems.

EVERGREEN SHRUBS FOR A SHADY PLACE (Bedder).—It is of little use planting shrubs beneath the branches of a Beech tree, as the shade is too dense to allow of anything thriving satisfactorily in such a position. About the outskirts of a tree, however, the following evergreens are likely to give satisfactory results: Common Holly, *Aucuba japonica*, common Laurel, *Berberis Aquifolium*, Tree Ivies and *Berberis stenophylla*. The ground should be well worked and the Beech roots cut back beyond the edge of the area to be dealt with, in order that the shrubs may have every possible assistance towards establishing themselves quickly.

TREATMENT OF HEDGE (Broadgates).—Your Thorn hedge could be improved by layering, that is, chopping the branches more than halfway through near the base and bending them over almost horizontally, securing them in position by means of strong stakes. This method of dealing with old hedges is more frequently practised in some counties than in others, and is very popular in Worcestershire. Not only do the layered branches grow again, but a good deal of young wood is made from below the cuts, which results, in about two years' time, in a strong hedge. When layering is practised, the branch system is reduced considerably at the same time, both for appearance and so that there shall not be too great a strain upon the partly-severed branches. A Holly hedge would be preferable to Laurel in the position you mention, but Laurel would grow into a hedge in about one-fourth the time which the Holly would take. Providing the work is done at once, either Holly or Laurel could be planted; otherwise, should Holly be selected, the work had better remain until the middle of next April. Laurels may, however, be planted at any time when the weather is open throughout the winter. Do not select very large plants. You will find that the smaller plants establish themselves more quickly than large ones, and form a better hedge in the end.

THE GREENHOUSE.

ANTS IN GREENHOUSE (R. E. C.).—Trace the ant to their nests and pour boiling water upon them. Carbon bisulphide may also be used with advantage.

PELARGONIUMS (Ignoramus).—The Pelargoniums have been attacked by some sucking insect, probably mealy bug. They will most likely produce healthy young growths now; but if not, spray with Quassia and soft soap.

NERINES NOT FLOWERING (A. S.).—According to your report of the treatment given the plants, they should have flowered well. The roots may possibly be at fault, in which case shake out the plants and repot at once, following in this and consequent respects the advice given by Mr. Elwes.

CARNATIONS IN WINTER (Pashbury).—In order to flower Perpetual-flowering Carnations in winter, a minimum temperature of 45° to 50°, with a light, buoyant atmosphere, must be maintained. They may, however, pass the winter safely in your pit, provided the weather is not too severe and that the watering is carefully done; but under these conditions you cannot expect flowers till the advent of more genial weather.

CYCLAMENS INJURED (Dams).—The maggots attacking the roots of the Cyclamen are no doubt those of the Vine weevil (*Otiorhynchus sulcatus*). The beetles which lay the eggs are common in early summer, and a considerable variety of greenhouse plants are subject to the attacks of the pest. We think the best plan would be to shake the plants out and pick out the grubs; but if it is desired to treat them in the pots, then the only thing likely to do any good will be to pour a few drops of carbon bisulphide into the pots, making a hole about half the depth

of the soil for the purpose. This is very poisonous, with-smelling and explosive, but the plants will not be likely to be injured unless the liquid comes into actual contact with a root, when that will suffer.

FIXING A CHRYSANTHEMUM SPORT (J. J.).—Cuttings should be encouraged, or the shoot which has produced the yellow flowers, by pinching off further buds, if any, and by keeping the plant in a favourable position in the greenhouse. The resultant shoots from the upper part of the plant should then be large enough to be taken off as cuttings. In all probability each shoot will have a tiny bud, which should be pinched off before the cutting is inserted. It is impossible to say whether the suckers from the plant will reproduce the sport, but it will certainly be worth your while to put them in and keep the plants separate from the others.

ROSE GARDEN.

ROSE DOROTHY PERKINS CANKERED (E. F. Campbell).—There is no known remedy save cutting away the affected growths. If you discard the old wood pretty freely, you will not be troubled much with the disease. You might give the soil a dressing of lime in the winter.

ROSES FOR EXPOSED POSITION (Miss McN.).—If you wish for a very strong grower, we suggest Conrad F. Meyer or Nova Zembla. These are Hybrid Rufoza Roses, and are very beautiful. Others of the same race, rather less vigorous, but yet quite suitable for your purpose, are Blanc Double de Coubert, Rose à parfum de l'Hay and Mrs. A. Waterer. Other fine Roses would be Lady Waterlow, Sarah Bernhardt, Mme. Wagram and Florence H. Veitch.

ROSES AND CLEMATIS (Bedder).—You will probably find Irish Glory the most suitable Rose to match Irish Elegance and Irish Beauty. Its colour is hardly what you desire, however, the description being "silvery pink, faded on the back of the petals with crimson," rather than deep crimson. It is very like Irish Elegance in shape and free-flowering qualities. Good kinds of Clematis to suit your purpose are C. Jackmanii superba, purple; C. Ville de Lyon, varmine-crimson; C. Queen Alexandra, mauve; and C. Jackmanii alba, white.

PREPARING A BED FOR ROSES (Pan).—You could not do better than add a good dressing of lime or powdered chalk. This will sweeten the soil and at the same time drive out the slugs. Dig the soil 3 feet deep, working in plenty of good manure and lime, the latter at the rate of 50z. per square yard, or, if you can obtain chalk easier, this at the rate of 3lb. to a square yard. If you use lime, it should be slaked, then evenly distributed and well incorporated with the soil. By preparing the bed at once it would be ready for planting the Roses in November, which is a much better time than the spring.

RUST ON ROSE LEAVES (H. W. S.).—The Roses are attacked by the Rose rust fungus (*Phragmidium subcorticatum*). We doubt whether spraying at this season of the year will do much good, or whether the attack now will do much harm, but as the fungus over-winters on the fallen foliage, it would be a means of prevention of damage to the shoots to collect and burn the leaves as they fall. This may be supplemented by spraying with a rose red solution of potassium permanganate in the spring if the rust should reappear. As it so frequently attacks wild Roses, it is practically impossible to get rid of it entirely.

THE BEST NOVELTIES INTRODUCED IN 1912 (Trent Bridge).—We are glad to know that the information we gave you last year has proved satisfactory to you. The following we can thoroughly recommend as being good all-round Roses: British Queen, Comtesse F. Hoyos, C. W. Cowan, Duchess of Sutherland, Earl of Gosford, Frau Ob. Piecy, General Superior à Janssen, George Dickson, Geoffrey Houslow (Hybrid Perpetual), Geoffrey Henslow (Hybrid Tea), Louise C. Breslau, King George V., Mme. C. Lutand, Mme. C. Chambard, Mme. E. Rostand, Maman Turbat, Mrs. D. Baillic, Mrs. Frank Bray, Mrs. Gordon Sloane, Mrs. H. Hawksworth, Mrs. Sam Ross, Mrs. Wallace H. Rowe, Ophelia, St. Helena, Sunburst, Suleina, Tito Illekayan and Verna McKay.

SELECTION OF ROSES (C. A. J. D.).—As you have such a good collection, you cannot do better than add the following: Reds—George Dickson, President Vignet, Earl of Gosford, Edward Mawley, Mrs. Walter Eastle and Prince of Arenberg. Yellows—Sunburst, Mme. C. Lutand, Lady Greenall, Paula, Alice de Rothschild and Cissie Eastle. Other colours—British Queen, Mrs. W. Christie Miller, Mrs. Charles E. Allan, Mrs. Wallace H. Rowe, Countess of Shaftesbury and Willowmere. Add some good top soil from a meadow and bury the turf. A good supply of spent Hops would be useful, and give a handful of bone-flour to each plant as you plant it. Feed in summer with fish-guano, very moderately, until the plants are established, but liberally to the older plants.

ROSE BABY DOROTHY (H. I.).—We believe there is no relationship between this Rose and Dorothy Perkins. Its correct name is Maman Levassour, and was a seedling from Mme. N. Levassour, we think. It has been superseded now by such Roses as Orleans. The Dwarf Polyantha Roses originated by crossing Rosa Polyantha *simplex* with a Tea Rose, the first variety raised being Ma Paquetette. Now, of course, novelties are raised by crossing the various kinds together, although some were raised by crossing the climbing *Multifloras* with other climbing Roses. For instance, Eugénie Lamesch originated from Achaia crossed with William Allen Richardson, and Mme. Norbert Levassour, from which such as Mrs. Cuthbertson and Orleans Rose have originated, was produced by crossing Crimson Rambler with the Dwarf Polyantha *Glorie des Polyantha*.

SELECTION OF ROSES (A. H. F.).—We gladly comply with your request, and from a decorative point of view, or, rather, as garden Roses, we should place the varieties you name in the following order of merit: Chateau de Clos Vougeot, Edward Mawley, Lady Pirrie, Lieutenant Chauve, George C. Wand, Rayon d'Or, Molly Sharnan Crawford, Mrs. D. Jardine, Beaute de Lyon, Earl of Warwick, Princesse Metchersky, Souvenir de M. de Zayas, Leslie Holland, General Schablikine and Mme. C. Souper. George Dickson is a grand Rose, but we take it this magnificent variety will be more in demand as a show flower. It is certain, however, that everyone will want to possess it. A few first-class recent Roses are Lady Greenall, Melody, May Miller, Countess of Shaftesbury, Rose Queen, Mayflower, Nathalie Böttner, Mrs. George Sawyer, Florence Haswell Veitch, Cissie Easlea, Willowmere, Ophelia, Louise Catherine Dreslau, British Queen, Bertha Gaulais and Sunburst. This latter has been splendid lately. It is a "great" Rose in spite of its tendency to produce pale blooms at times. The botanical name of the Christmas Tree or crimson Struce Fir is *Abies excelsa*.

FRUIT GARDEN.

SILVER-LEAF ON PLUM TREE (Whitehouse).—The leaves of the Plum tree are attacked by the silver-leaf disease. The shoot on which these leaves occur should be cut out and burned, but it may be well to leave it till next year to see whether it recovers, as it has been bearing well this season. If not, destroy it at once. No certain cure is known for this disease, which is of fungus origin.

SCALE ON PEACH LEAVES (Peach Tree).—The Peach foliage has been very badly attacked by the Peach scale insect and by red spider. Spray the trees now with a solution of potassium sulphide, 1oz. to three gallons of water, or, if in a house or case, fumigate twice at an interval of three days. In winter thoroughly cleanse the trees and the walls, removing all the scale insects completely.

PLUM RUST (M. R. P.).—The Plum tree is attacked by the Plum rust fungus, *Puccinia pruni*. This fungus, like many of the other rust fungi, passes part of its life-history on Plums, part in the spring of the year, on Anemones. It forms little cups on the foliage of the latter, scattered in close groups and filled with spores. These spores spread the disease to the Plum. The removal of all Anemones from the neighbourhood of the Plums would probably reduce the trouble. If this cannot be done, it would be well to spray the trees with ammoniacal copper carbonate at fortnightly intervals, beginning at the end of May.

ORCHARD TREES NOT DOING WELL (Hortus).—What you propose to do is on sound lines and excellent. The trenching and clearing of the surface of the ground of the turf over the roots of the trees alone must greatly benefit them. The following formula of artificial manures for Apples, Plums and Pears is by Mr. Edmund Tonks, and is, we believe, scientifically correct and excellent: Superphosphate of lime, 12lb.; nitrate of potash, 10lb.; chloride of soda, 4lb.; sulphate of magnesia, 2lb.; sulphate of iron, 1lb.; and sulphate of lime, 5lb. This should be well mixed together and applied at the rate of a quarter of a pound to the square yard. We presume you wish to have an artificial manure more particularly to mix with the soil while trenching proceeds. Perhaps the following would suit you better (it is effective, we know), reserving the other formula for annual top-dressings: 12lb. of superphosphate of lime and 12lb. of kainit. Add 4oz. to each square yard, mixing it with the soil as trenching proceeds.

APPLES TRAINED ON WIRE TRELLIS (Wirswell).—In the first place, the varieties of Apples, of which you sent us such poor samples, are more subject to attacks from red spider than are most other sorts. The foliage, we find, is badly infested with red spider and American blight. In the second place, red spider is very prevalent this year, on Apples especially, on account of the long drought from which we have suffered. You do not say how near the trellis is to the boarding. If it is, say, within 3 inches or 4 inches, then we think there is some truth in what you say as to the boards having something to do with the failure, not because they are crossed particularly, but because there is not a sufficiently free circulation of air among the branches, causing the air to become too hot. Apples never succeed well when trained against walls or fences. The position is too hot and the circulation of air too restricted for them. The trellis should be at least 6 inches or 7 inches from the fence for Apples. Pears and Plums will stand the heat and confinement better. The Apples, we think, would do better without the fence, leaving only the wire fence, converting it into an espalier trellis. Other causes may be responsible, such as the soil being too poor or light, the border too dry, or the cropping too heavy. You can do nothing to the trees now to rid them of spider and the blight except to burn all the affected leaves as they fall, and towards the end of November or early in December, after the trees are pruned (burn the prunings), they should be sprayed with the following mixture (called the Woburn Winter Wash): Soft soap, half a pound; paraffin, 5 pints; caustic soda, 2lb.; and water, 91 gallons. This wash will thoroughly cleanse the trees of all pests or growth of any kind with which they may be infested. The way to prepare it is to dissolve the soap in warm water, churn the paraffin into it, and then shake in the caustic soda, mixing the whole well together and applying it with a syringe or garden engine. The hands and clothes must be protected at the time of using it, as it is of a burning nature. The mixture must be kept churned while it is being applied, to keep the paraffin in solution.

PEACH TREE UNSATISFACTORY (Annon).—It is difficult to understand the cause of failure in the cropping of your Peach tree. Your inside border is narrow. Are you quite satisfied that the roots have not suffered from the want of water at any time? The trouble, we feel sure, arises from the tree having received a check of some sort, which affected adversely the functions of the fruit-buds and flowers, ending in imperfect fertilisation of the flowers; hence failure in proper fruit-setting. Never let your tree approach to dryness at the roots, winter or summer. Take a lesson from trees growing outside, which are often sodden in many winters and are certainly never dry. These seldom or ever drop their fruit. Are you careful to keep your tree as cool as possible during the winter, or is the house subject to fluctuations of temperature? This will often account for such failures. Keep your tree as cool as possible, with plenty of air on the house day and night in favourable weather, and let the tree come into bloom naturally without any forcing or excitement. Widen your inside border by 18 inches. Examine the roots in front of the border when they are exposed, and shorten the ends of each. If there are any long, fibrous ones, cut them well back to within 3 feet of their base. Peach trees are often much benefited by root-pruning. We should certainly not destroy the tree. It should go on improving for another twenty years. The following is a good Peach soil: To one barrow-load of good fibrous loam inclining to be of a heavy nature add 2lb. of Thomson's or some other approved artificial manure, a gallon of lime, a peck of brick-ends, broken small (size of a hen's egg), and the same of mortar rubble, broken small. The loam should be broken up with the hands into pieces the size of one's fist, and all mixed well together.

KITCHEN GARDEN.

MANURE FOR CABBAGES (R. E. C.).—Use farmyard manure in preparing the ground. When fear of serious frost is past and the Cabbages begin their spring growth, apply nitrate of soda at the rate of 1oz. to the square yard.

INJURY TO LETTUCE (A. P.).—The Lettuce is attacked by the root aphid, which is often abundant on this plant, especially in dry seasons. Watering with soot-water may do some good, or you might fork in a little Apterite or Vaporite or some other naphthalene preparation to drive away the insects.

MISCELLANEOUS.

STANDARDS AND HALF-STANDARDS IN FOLKESTONE (J. E.).—You do not say whether you mean Roses or fruit trees. If the soil is very sandy where you are, neither would do well unless good loam were carted for them. Apart from soil, and possibly wind, we do not see why standards of either Roses or fruit trees should not do in the district.

CREEPER FOR LOW BRICK WALL (A. H. R.).—*Escallonia macrantha* is as pretty as anything for a wall such as yours, and it can be kept to any height required by clipping or cutting it back. *E. oxoniensis* or *E. phillypina* is also good. *Ceanothus Gloire de Versailles* kept to the height desired is also pretty. If you care to form pockets on the face of the wall, you might have some of the trailing alpines, such as *Dianthus*, *Helianthemum*, *Campanulas*, *Arenarias* and *Androsace lanuginosa*.

SIBERIAN CRAB AND OTHER QUESTIONS (F. B.).—You may move your Siberian Crab tree as soon as the leaves have fallen. Providing the work is carried out carefully, the tree will not suffer. Your Carnations are evidently suffering from a fungous disease, but it was impossible to judge satisfactorily from the specimen sent. The shoots have probably been injured by wireworms. These may be trapped by burying Potatoes in the soil to a depth of 3 inches and examining them every second day. The only way to eradicate earwigs is to trap them. This may often be done by placing a little hay in flower-pots and inverting the pots on stakes from 2 feet to 4 feet high. The Rose sent for determination is apparently *Auguste Barbier*. We are at a loss to account for the flowers becoming deformed. As you suggest, the cold spring may have had something to do with it.

NAMES OF FRUIT.—*Tottle*.—Mank's Codlin.—1. *R. Strickland*.—2 and 3. Hawthornden; 4, 5 and 11. Wellington; 6. Braddick's Nonpareil; 7. Ribston Pippin; 8. Bismarck; 9. rotten when received; 10. Cox's Orange Pippin.—*W. B.*—1. Tower of Glamis; 2. Adam's Pearmain; 3. Fearn's Pippin; 4. Cellini Pippin.—*E. P.*—1. Cox's Pomona; 2. Lane's Prince Albert; 3. King of the Pippins; 4. Cellini Pippin; 5. Lady Sudeley; 6. Reinette du Canada; 7. Hawthornden; 8. Cox's Orange Pippin; 9. Wellington.

NAMES OF PLANTS.—*Enquirer, Stamford*.—1. *Ternstroem montanum*; 2. *Dianthus smensis* variety.—*J. G. W.*—1. *Polygonum amplexicaule*; 2. *Campanula punctata*; 3. *Hibiscus sriacus*; 4. *Linaria purpurea*.—*S. M.*, *Southburn*.—*Pentstemon barbata*; *Rosa Polyantha* variety.—*Rec. H. J. De S.*—*Cypripedium macrotarpum*.—*W. Dawson*.—1. *Sutherlandia frutescens*; 2. *Cotoneaster microphylla*; 3. *Pernettya mucronata*; 4. *Berberis stenophylla*; 5. *Escallonia* species; 6. *Cotoneaster horizontalis*; 7. *Olearia Haastii*; 8. *Aucuba japonica*.—*H. N.*—*A.*, *Lidum auratum*; *B* and *C*, varieties of *Lilium speciosum*; *D*, too poor to identify.—*K. J., Batham*.—The peculiar growths on the Juniper branch are abnormal fruits. The shrub sent for determination is *Ledum palustre*.—*M. R. H. Allen*.—*Azara microphylla*.—*Moss*, *Azolla caroliniana*.—*Ida H. Jackson*.—*A.*, *Festuca ovina vivipara*; *B.*, *Lycopodium alpinum*.—*Parley*, *Senecio tangetius*.

SOCIETIES.

ROYAL HORTICULTURAL SOCIETY'S FRUIT SHOW.

THE nineteenth autumn show of British-grown fruits was held on September 25 and 26 at Vicent Square, Westminster. The exhibition was notable for the high standard of quality among the Apples, which, although not so highly coloured as in some years, were clean and well finished. Pears, however, were somewhat scarce, but this was in some measure compensated for by the keen competition in the Apple classes. The indoor fruit was of very high quality, the Grapes in particular being fine and well finished.

DIVISION I.—FRUITS GROWN UNDER GLASS OR OTHERWISE.

Open to Gardeners and Amateurs Only.

The first prize silver cup for a collection of nine dishes of ripe dessert fruit was secured by the Duke of Newcastle (gardener, Mr. G. Barker), Clumber, Worksop, with a well-finished collection of ripe and highly-coloured fruit, consisting of two bunches of Grapes Muscat of Alexandria and the same of Madresfield Court. Pears were well represented by splendid dishes of Pitaston Duchess and Durondeau; Melon by Emerald Gem, Apples by Cox's Orange Pippin and King of Tompkins' County, and two excellent dishes of Peaches by Barrington and Nectarine Peach. Second, Lady Henry Somerset (gardener, Mr. G. Mullins), Eastnor Castle, Ledbury, who also staged a most creditable display, the Black Hamburg Grapes being large in both bunch and berry and perfect in colour. The other varieties shown were Apples Cox's Orange Pippin and Rival, Pears Marguerite Marillat and Doyenné du Comice, Peach Devonian and Melon Comtesse. Third, the Earl of Harrington (gardener, Mr. J. H. Goodacre), Eivaston Court, who also staged a very choice collection, including a dish of Pineapple Nectarine.

Lord Hillingdon (gardener, Mr. J. Shelton) Sevenoaks, Kent, succeeded in taking the first prize and silver cup for a collection of six dishes of ripe dessert fruit. The Grapes were of the highest quality, and all other kinds well grown and highly-coloured specimens, the varieties being Grapes Muscat of Alexandria and Muscat Hamburg, Peach Lady Palmerston, Apple Cox's Orange Pippin, Fig Negro Largo, and a seedling Melon. Lord Bolper (gardener, Mr. W. H. Cooke), Kingston Hall, Derby, was a good second, the varieties staged consisting of Grapes Gros Colmar and Muscat of Alexandria, Melon Hero, Peach Sea Eagle, Apple Cox's Orange Pippin, and Pear Louise Bonne Jersey. C. A. Cain, Esq., J.P. (gardener, Mr. T. Pateman) Welwyn, was awarded third in this class.

The class for six varieties of Grapes, two bunches of each, probably created the greatest interest of the whole show, as the group which won the first prize and silver cup (see illustration) for the Duke of Newcastle, contained two magnificent bunches of Gros Guillaume, which received the admiration and highest praise from every visitor to the show. The bunches were not only large in point of size, but also in berry, the whole being beautifully coloured and well finished. The other varieties shown in this exhibit were Black Hamburg, Madresfield Court, Gros Colmar, Muscat of Alexandria and Buckland Sweetwater, all of splendid quality and finish. The Earl of Harrington came second with some smaller but well-finished bunches of Muscat of Alexandria and Golden Queen, representing the white Grapes; and Madresfield Court, Gros Maroc, Muscat Hamburg and Black Hamburg. The third prize in this class was won by C. Bayer, Esq. (gardener, Mr. E. C. Wickens), Tewkesbury Lodge, Forest Hill, S.E., who showed a most worthy collection.

In the class provided for two bunches of Grape Black Hamburg, the first prize was awarded to Lord Hillingdon for two well-finished bunches; second, Lady Henry Somerset; third, the Duke of Newcastle.

H. St. Maur, Esq. (gardener, Mr. G. Richardson), Newton Abbot, was successful in gaining first prize for two splendid bunches of Mrs. Pince, the second prize falling to Lady Henry Somerset, who also obtained first for two large and well-finished bunches of Black Alicante, the Marquis of Salisbury (gardener, Mr. H. Prime), Hatfield House, coming second with some good bunches, and W. G. Raphael, Esq. (gardener, Mr. H. H. Brown), Castle Hill, Englefield Green, third.

The Duke of Newcastle gained the leading honours for two bunches of Madresfield Court, the second and third prizes going to the Earl of Harrington and Lord Hillingdon in their respective order of merit.

The first prize for two bunches of Grape Prince of Wales was won by Sir Watpole Greenwell, Bart. (gardener, Mr. W. Linford), Marden Park, Caterham, this being the only prize awarded in this class.

For two bunches of any other black Grape, Lady Henry Somerset took the premier position with Gros Maroc, the second being awarded to Colonel the Hon. C. Harbord (gardener, Mr. W. Allan), Gunton Park, Norwich, with the same variety, and third to the Marquis of Salisbury with Apple Towers.

Sir Edward Durning-Lawrence, Bart. (gardener, Mr. W. Lane), King's Ride, Ascot, secured the first prize and silver Knightian medal for two bunches of Muscat of Alexandria, Colmar, the Hon. C. Harbord coming second, and G. Miller, Esq. (gardener, Mr. J. Kidd), Newberries, Radlett, Herts., third.

In the class for two bunches of any other white Grape, the Duke of Wellington, K.G. (gardener, Mr. A. G. Nicholls), Stratfieldsaye, won first place with the second largest bunches in the show, which were well finished and of good quality, the variety being Calabrian Raisin. C. A. Cain, Esq., J.P., followed with Lady Hunt; and H. W. Henderson, Esq. (gardener, Mr. F. L. Pike), King's Langley, third with Foster's Seedling.

EDITORIAL NOTICES.

Every department of horticulture is represented in **THE GARDEN**, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in **THE GARDEN** will alone be recognised as acceptance.

Office: 20, Tavistock Street, Covent Garden, W.C.

NOTES OF THE WEEK.

October Roses.—Apart from such Polyantha Roses as Jessie, Orleans and Katherine Zemet, which are always good in autumn, many of the Hybrid Teas and pernetianas are this year flowering well later than usual. Marquise de Siney, Duchess of Wellington, Mme. Léon Pain, Pharisäer, Gloire de Dijon, Mrs. A. Munt, Mme. Ravary, Betty, Königin Carola, Souvenir de Stella Gray, Rayon d'Or and Mme. Abel Chateaux are a few that have particularly good flowers on them as we are going to press.

A Handsome Knotweed.—This family of plants contains many beautiful species, from dwarf alpine ones, 3 inches to 4 inches high, to the tall Polygomon sachalinense and the climbing P. baldschianicum, 12 feet to 20 feet high; but the most ornamental one flowering now is the many-spiked Knotweed, P. polystachyum, with its panicles of pinkish white flowers. Either in a mass by itself, where it makes a very bold display, or in the herbaceous border it is a very ornamental subject, and it will give an annual display with little attention.

Protecting Christmas Roses.—The original Christmas Rose (Helleborus niger) does not bloom till the Christmas season, but H. n. altissimus, also known as maximus and major, a variety in every way superior to the type, often begins to flower early in October, and goes on for a long period. Although quite hardy, the blooms come a purer white and are immune from dirt if protected by a light frame. Abundance of air should be admitted, however, and a good plan is to tilt up the frame by placing a brick under it at each corner.

Flower Garden Combinations.—Those who seek to produce great flower contrasts in the garden should make note of two plants which by reason of habit and the merit of profuse as well as abundant flowering would appear well suited for purposes of display. The plants we have in mind are the brilliant scarlet Salvia Glory of Zurich and the pure white Anemone-flowered Marguerite, better known perhaps as Chrysanthemum Mrs. Sander. For effective work it may not be necessary to mix the two or even to border the one with the other, a better way being, perhaps, to plant a bed of each in near proximity, and so murmur into greater purity or brilliance the finer attributes of these unique subjects.

A Pretty October-Flowering Shrub.—The fine mild weather of the last fortnight has been very favourable for the late-flowering Lespedeza Sieboldii. At its best, with tall, slender stems 4 feet to 5 feet long, each terminating in a large inflorescence, it is particularly attractive, for there are very few shrubs flowering in October. L. Sieboldii is a native of North China and Japan. During most winters the young growths are killed

to the ground, but, even if only the ends are damaged, it is worth while cutting the stems down to obtain the vigorous young growths which push up from the base. The leaves are trilobate, the flowers, which are very freely produced, being rosy purple, borne on long-branched terminal panicles. Unfortunately, this plant has several synonyms, a favourite nursery name being Lespedeza bicolor, while another is Desmodium penduliflorum.

Increasing the Double-Flowering Arabis.—The double-flowering Arabis is too well known to need any recommendation for spring bedding, but many people annually go to the trouble of propagating it from cuttings. This is quite unnecessary, for pieces taken from the old plants now and dibbled in the beds or borders where they are required to bloom will be found to make good plants and flower much freer than those raised from cuttings.

A Late-Flowering Shrub for a Sheltered Corner.—One of the most showy of late-flowering shrubs is Clerodendron tomentosum, or C. Bungei as it is sometimes called, and although it is not a hardy shrub—for seldom in the open does it stand the winter without dying back like a herbaceous plant—yet, if it is given the protection of a wall, or, better still, the corner of two walls, it will make a fine, handsome specimen. It is not essential for it to have a south wall. The plant we have in mind is growing in a corner with a north-east aspect, and is 10 feet high. It quite fills up the space, being 5 feet through, and is now laden with dense terminal corymbs of rosy pink flowers. It is well worth a place outside in such a position. Other handsome, nearly hardy Clerodendrons are C. trichotomum, with white flowers which are a great contrast to the red inflated calyx, and its variety Fargesii, which is more compact.

Ornamental Fruits in the Garden.—Certain hardy trees and shrubs are this autumn bearing an unusually heavy crop of fruits. Both as large bushes in the open and as a climber trained to a wall the branches of Pyracantha (Crataegus) coccinea are laden with orange red berries. Unless, however, the bushes are covered with nets, the birds will secure most of the fruits by the end of October. The Sea Buckthorn, Hippophae rhamnoides, with its grey, Willow-like leaves and orange-coloured fruits weigh down the branches. Among numerous attractive bushes of Cotoneasters, C. frigidula is the most conspicuous, with quantities of red fruits. The Spindle Tree, Euonymus europaeus, with coral red fruits; Berberis vulgaris, the Common Barberry; the waxy white fruits of Symphoricarpos racemosus, the Snowberry; Pyrus Kingo, with golden yellow Crab-like fruits; the heavily-laden bushes of the Dog Rose, Rosa canina, the large, scarlet red fruits of R. canina suberistata in particular; and the Cocks spur Thorn, Crataegus Crus-galli, with scarlet fruits and orange-tinted foliage, each and all add to the interest and attractive character of the garden in autumn.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Crocus caspius.—This is in flower here now (October 2) in a spot where it is established. Corms transplanted this summer will not be out just yet. It is one of the largest and finest of the autumn-flowering species, pure white inside, the exterior of the petals pale mauve. Here we find it a very free seeder, and I raise a number of seedlings every year, which, however, do not flower till three years old. Recently I have used the pollen of *C. hyemalis* Foxii and one or two other species on it, and am now awaiting with interest

exhibition from the leading exhibitors of the country.—HENRY MERRYWEATHER, *Southwell, Notts.*

Saxifraga burseriana.—Really, since we are all agreed as to how we each prefer to grow or not to grow *Saxifraga burseriana*, it may well seem waste labour to go on exchanging facts about the plant against contradictions, no matter how emphatic. At the same time, I cannot feel it would be good for anybody if I acquiesced silently in being given the lie with quite the candour affected by Mr. Elliott. This great and earnest man, in the ardour of dispute, has been misled by analogy, that perilous charmer. He has seen (from the tram) sunlight streaming into the mouth of the Salurn Klamm; yes, indeed, so have I—and felt it, too! Now it drink streams into my

torrid stretches at the mouth of the gorge; not only for this reason perhaps, but also because that mouth is occupied by true, coarse scree. With regard to the geological lecture administered by Mr. Elliott, in the first place I think a closer acquaintance with the fine silty ridges in the shadowed interior of the Klamm would cause Mr. Elliott to be less certain as to the origin of those banks; in the second, whether washed down by water or up by water, the soil there is so unlike any other detritus—utterly different from any—and so utterly alien from the coarse composition of scree that it is only, and precisely, comparable to the fine silts that lie in wavy ripples over the Forcella Lungieres or the Passo delle Selle. Therefore in describing such for the horticultural benefit of those who have not seen, or for those who have, but forget, it is certainly allowable to paint it as silt, even as even Mr. Elliott himself, I imagine, applies the word "moraine" to a horticultural compound which in reality has no relation to the rounded, water-worn desolations whose convenient name it bears, but is in relation to the conditions of quite a different deposit, the sharp and fertile accumulations of fallen shingles on the highest slopes and hollows (if I may be allowed to use the word shingle without being told that it is only admissible of Brighton Beach). Mr. Elliott, however, mistakes the reason why *S. burseriana* grows in the fine silt of the Salurn Klamm. It does not do so because I say it, not even because I have said it twice; but because I have twice very carefully noticed and collected it there so growing, and duly record the fact for the interest of such people as lay greater weight on repeated observation than on even the most aquiline of glances cast from an express train proceeding in full career perhaps half a mile from even the entrance of the gorge (for such, I may suppose, was the tram that took Mr. Elliott, or rather, as I had better say, conveyed him). However, these are unprofitable matters. Mr. Elliott regrets that he was unable to give me his corroboration. Even had my records stood in need of it, the blow of this denial would still be softened to me by Mr. Elliott's proper admission that his remarks have to be conditioned by the considerable qualification "as far as I remember." Now, however far "I remember" may go, such a recollection, dim of clear, of two or three seasons since cannot well enter into competition with the actual observation of the current year, deliberately sought with an eye to getting the facts correct. Therefore, for what the information may be worth to the cultivator in the way of interest, it may be taken that *S. burseriana*, in Nature, certainly luxuriates in at least one famous station in fine liny silt and in a shady gorge. In the Schlern Klamm, "as far as I remember," the plant tends to be more saxatile, as the gorge is wider, and therefore less overshadowed by its walls; while on the Hoch Obir the minor form grows in enormous masses, on the under side principally, of turf laps along the neck of the mountain.—RICHARD FARRER.

ROSE-GROWERS OF BYGONE DAYS

Standing, left to right: Mr. W. Carter, Mr. H. Merryweather, Mr. Whiston; other two not known. Seating, Mr. Bull, Mr. Charles Galea, Mr. E. R. Cant, Mr. Newell.

the flowering of what I trust will turn out to be hybrids. F. HERBERT CHAPMAN, *Kyle*.

Rose-Growers of Bygone Days.—In the early seventies—a time when great advance was made in the introduction of new varieties of Roses—Mr. Quiller of Aston Park, Birmingham, promoted and held some first-class Rose Shows, and one condition was a £10 penalty if a grower entered and did not exhibit. On one of those particular occasions I well remember having a very enjoyable luncheon, when our old and esteemed friend, the late Benjamin Cant, took the chair, and someone proposed that we should have our photograph taken in a group, a copy of which may be of some interest to your readers. I well remember we had a fine meeting of all Rose-growers and a splendid

mouth of Mr. Elliott's, it streams into him of me *ex hypothesi* unless we reject it. But sun, streaming into the mouth of a gorge, by no means necessarily streams into the gorge itself. And whereas the mouth of the Salurn Klamm can indeed be seen from trams, and felt by closer inspection to be one of the hottest and most sun-flogged places that an alpine afternoon or midday can discover, the interior of the Klamm rejoices in wholly different conditions, and may fairly be described as a sunless gorge—not sunless, indeed, as a cavern measureless to man, but sunless in only having a brief and inconsiderable daily share in that luminary. And it is significant that only when you arrive at the Klause does the *Saxifraga* begin to occur, quite retusing the more open and

mouth of clear, of two or three seasons since cannot well enter into competition with the actual observation of the current year, deliberately sought with an eye to getting the facts correct. Therefore, for what the information may be worth to the cultivator in the way of interest, it may be taken that *S. burseriana*, in Nature, certainly luxuriates in at least one famous station in fine liny silt and in a shady gorge. In the Schlern Klamm, "as far as I remember," the plant tends to be more saxatile, as the gorge is wider, and therefore less overshadowed by its walls; while on the Hoch Obir the minor form grows in enormous masses, on the under side principally, of turf laps along the neck of the mountain.—RICHARD FARRER.

Rose Irish Elegance in Scotland.—In common with many others, I have read with keen interest the correspondence in the columns of THE GARDEN regarding this Rose, which I had not seen. It was, therefore, with pleasure that I came across several plants of it the other day in the gardens of Lady Cathcart at Cluny Castle, Aberdeenshire, while spending a holiday in that district. The plants showed great vigour, and Mr. McLeod, the head-gardener, told me that they had bloomed very freely. There was sufficient bloom left to show the true character of this beautiful Rose.—**CALEDONIA.**

Gypsophila Rokejekii.—This is a tall, lax-habited species well worth introducing into mixed borders. The flowers are about the same size as those of *G. Stevenii*, and pink. The lank stems, if left to themselves, shoot up to proportions far beyond what the amenities of present-day gardening admits, and it is therefore essential to cut each one as it attains the desired height, which, as well as checking growth, causes the laterals to spring out and form a somewhat bushy plant. It flowers from the end of August till the end of the floral season, and is easy to propagate by seed.—**R. P. B.**

Outdoor Figs.—With reference to the note in THE GARDEN of September 20, page 470, respecting the above, it may interest some readers to know that here on the southern border of Yorkshire we have trees of Figs Brown Turkey and White Marseilles growing on a south-east wall and yielding good fruit. The soil in which the trees are growing is of a sandy nature, and although this season (and noticeably this district) has been exceptionally dry, no watering has been done. During the winter the roots are heavily mulched and the branches protected by mats; but, apart from this, no special treatment has been deemed necessary. I may mention that the tree of Brown Turkey is about twelve feet high and has a spread of about twenty-five feet.—**H. TURNER, Serlby Hall Gardens, Bawtry, Yorks.**

Campanula fragilis.—Mr. Arnott writes of this well-marked species on page 473 as being "of the same class as garganica," from which, of course, it is most distinct. Indeed, the two plants have nothing in common. *C. garganica* is of almost matlike density, and provides an innumerable host of small, very starry flowers, while *C. fragilis* is a comparatively sparse-growing plant, the much larger flowers of saucer-like outline totally unlike those of the other species named. Hence one is a little puzzled by the remark. The true *C. fragilis* is quite one of the most "touchy" of its race, so much so that attempts to divide it must be undertaken with care. A "white form" is also referred to in the paragraph, which I do not appear to recall. If good and pure, it would certainly be very charming.—**E. H. JENKINS.**

Rose-Buds Dropping Off.—We have lost so many buds this year, especially during their formation for the second flowering, that I would like to ask, if space can be spared, whether other readers of THE GARDEN have shared a similar fate? Sometimes the buds have been almost black, at other times yellowish, and of sizes varying from a pin's head to an ordinary Sweet Pea seed. We have never been able to track any insect in the act of damaging them, and the plants have been regularly syringed with one solution or other, besides which the plants are normally healthy. In some cases the buds would be quite right one day, then in another day or so gone, or would fall immediately if the bush or shoot was handled,

and frequently the loss would be from a clean and strong growth. Our final supposition was that the falling off must be due in some way to climatic conditions. Can anyone offer any better explanation? I ought to add that the plants have been regularly watered, so there is no fear of drought.—**C. T., Hightate.**

Rose President Vignet.—This new Hybrid Tea, from Pernet-Ducher in 1911, has been extra good with me of late; in fact, it is one of the very best reds at this season; a capital grower and bloomer, flowers large and solid, also possessed of an especially sweet perfume. Carmine, shaded with poppy red, is the best description I can give, and as it was good last autumn as well as this, it will probably take a high position as a good late red bloomer.—**A. P.**

Salvia uliginosa as a Hardy Plant.—In reference to your illustration and note in THE GARDEN for September 27, page 484, it may interest readers to know that this plant has been growing now for several years in the herbaceous ground at the Botanic Gardens, Cambridge, without being in any way affected, either in the winter or early spring, by frosts. Although the individual flowers are of a pleasing blue, the plant itself is of a somewhat straggling habit, from 5 feet to 6 feet high, and hardly to be compared with some of the other members of the Sage family.—**F. G. PRELSTON, Botanic Gardens, Cambridge.**

Musk Losing Its Scent.—In your issue of August 23, page 418, "E. A. P." enquires if Musk still retains its scent in its native haunts. I enclose seeds of a variety growing on Vancouver Island. This resembles *Mimulus moschatus*, and grows luxuriantly in moist places, but is not scented. I have never found a scented variety here.—**T. SHEWARD, Hillbank, Vancouver Island, British Columbia.**

—In your issue for August 23, page 418, there was a very interesting article on "Musk Losing its Scent," by "E. A. P.," who says he would like to know whether it is still fragrant in its native haunts and by what insects it is fertilised there. In my garden here there are quantities of wild Musk, which I often pull up by handfuls, for it grows so quickly that it smothers the other plants. It flowers so freely and looks so pretty that I leave a patch here and there, but, alas! it is quite scentless. I am no botanist, so cannot say anything about the variety, but to all appearances it is just the same plant we used to grow in pots at home in the Old Country, and no doubt "E. A. P." will be considerably amused to learn that a week or two before reading his article in THE GARDEN I purchased a tiny pot plant from a local nurseryman, who assured me that it was "real English Musk," grown from seed sent to him direct. This certainly had a slight perfume when I bought it, but I regret to say the plant was neglected and has died down. With reference to the insects that fertilise it here, I should say it must be the mosquitoes which perform that duty, as they abound and are most plentiful where the Musk plant thrives best.—**C. R. THURSTON, Vancouver, British Columbia.**

FORTHCOMING EVENTS.

October 16.—Royal Jersey Fruit Show. North of England Horticultural Society's Show at Leeds (two days).

THE IMPROVEMENT OF GARDEN ROSES.

WHAT does the amateur rosarian want from the raisers of new Roses, and on what lines ought he to press for improvement? In the abstract the questions seem easy enough to answer.

A visit to any of our big shows would indicate that we already possess flowers of great beauty and variety, both in form and colour, so that we might be tempted to say, as Rivers did sixty years ago, that it seems difficult to expect anything more beautiful; while the florists' shops show us that we may now have Roses of great beauty nearly all the year through. Yet, when we come to examine our own and our friends' gardens, we become conscious that there is considerable possibility of improvement in our garden Roses. At the same time, we can only in reason hope to proceed by steps, and these steps must be practical ones; that is to say, if we hope to get some special quality impressed on our Roses, we must look for it, or for some indication of it, in the plants we already possess.

Now the first quality to which I would ask our hybridisers to devote their attention is continuity in flowering. No one can deny that great steps have already been made in this direction. It is only necessary to go into an old-fashioned Rose garden, as I did in the month of September, where the plants are those of twenty or thirty years ago, that is, mostly Hybrid Perpetuals, and see them all looking very green and healthy, with great, long shoots, but scarcely a flower worth looking at among them, and then compare this with a Rose garden of modern plants gay with a profusion of flowers and colour. The gain is considerable, but it might be extended. All the Hybrid Teas, even the best of them, have a flowerless period, often of some weeks, succeeding each burst of bloom. Liberty, Mme. Ravary, Lady Ashtown, Mme. Abel Chatenay, Caroline Testout, Joseph Hill, Mrs. E. G. Hill and Mme. Leon Pain all cease flowering for a time while the buds for the next crop of flowers are growing. My special affection for Richmond is, I think, largely founded on the fact that in its case this flowerless period is less than with most other varieties. Even the Teas, like Mme. Lambard and Mme. Antoine Mari, possess the like defect, though Molly Sherman Crawford perhaps shows it less than most of them.

I decline, however, altogether to think that this condition is a necessary one. We do now possess in our gardens three Roses in which there is actually no cessation of flowering. My beds of Jessie, Mrs. Cutbush and Orleans Rose have been full of flower without a break ever since the plants came into bloom towards the end of June. If these charming little plants only possessed beauty of form in the flower as well as continuity, we should be a great step in advance; but, unfortunately, they do not, and we still wait for a Hybrid Tea of fine shape and colour to equal them in continuity. Of course, in order to secure this continuity in the varieties I have named, cultivation must be attended to. They must be planted in really well-made beds, and have their flowers carefully removed as they go over. Also, if a period of drought supervenes, as has happened this summer, they must have occasionally a thoroughly good soaking of water. If planted in badly-made beds, or if neglected, they will have their flowerless

periods like other Roses. Possibly Mr. Pemberton's beautiful new seedlings Danæ and Moonlight may help us in the desired direction; but down to the present I have not tried them.

Disease-Resisting Roses Wanted.—Another direction in which we may look and hope for improvement is in that of freedom from disease. No one but the rosarian knows how much time and trouble is lost in the attempt to keep down mildew, and how hopeless and disreputable a Rose garden looks where the attempt has failed and the fungus is disfiguring the foliage. Now we already possess several Roses which are practically immune from this disease. For instance, Lady Waterlow, Rayon d'Or and the old Rose Mrs. George Dickson appear to be unaffected by mildew, though they may fall a prey to black spot. Some Roses are great offenders in their liability to mildew. If we could find a Killarney, an Irish Elegance or a Mrs. Herbert Stevens that was immune from this pest, how great would be the advance, for each of these in its way has a form of great beauty! In its effect on the constitution of the plant in future years, black spot appears to be a more serious enemy of our Roses even than mildew, and, moreover, it is far less easily dealt with. Few, if any, Roses appear to be immune from this trouble, but some are much more subject to it than others. The Lyon Rose in my garden has been a great offender in this respect, and White Maman Cochet and Dawn are easily affected by it.

There is a third direction in which we may look for improvement in our Roses of to-day, and that is in the development of plants that will readily and under moderate conditions of culture yield us flowers of good form and decided colour throughout the season, be it wet or fine, when grown as cut-backs. There are many Roses which more or less frequently give fine flowers on maiden plants which are nearly useless as cut-backs. These the wise man will turn out of his garden so soon as he has been able to give them a fair trial, and they die a natural death before many years are past after their introduction. But there are many others, and among them some of our best Roses, which are by no means good throughout the season. Richmond is lovely in its first bloom and good again in autumn; but the summer flowers, particularly in a year of summer drought like the present, are often of poor quality and colour, and though they may look well in the distance, will stand no close inspection. Mme. Ravary, again, and several varieties of similar colouring, including the beautiful Prince de Bulgarie, when the autumn rains and cold nights begin to arrive, seem to get all the colour washed out of them and lose character altogether; while there are others, like Duchess of Wellington, Mme. Edmee Metz, Mme. Segond Weber and many of the Teas, with petals of thin substance which are most beautiful when the weather is fine, but hopeless

if it be wet and they are unprotected. I can think of few Roses which meet my requirements in this respect better than Mme. Abel Chatenay. It almost always produces well-shaped flowers, and though no doubt its colour is sometimes better than at others, it is seldom a poor colour, and it is no doubt to these virtues that its immense popularity is due. It has other defects, it is true, but in the qualities I have named, perhaps it is as yet unsurpassed.

Now how are we to secure the production of Roses with these desirable qualities—continuity of flowering, freedom from disease, and the easy production of good flowers throughout the season? Clearly we shall get no assistance from the shows, where none will display any but the most perfect flowers that he can produce; nor from the descriptions given by the raisers, who commonly predicate all these qualities of their seedlings, and I am willing

PLAN OF A ROSE GARDEN WITH LILY POOL IN THE CENTRE.

to believe that the raiser's description may often have been justified by his experience of the maiden plants of the new variety in his own garden. But the amateur knows only too well that when the plant is transferred to his own garden, the description but too frequently differs materially from his own observation of the new Rose.

It seems that as matters are now arranged it is to the amateurs chiefly and finally that we must look to secure the results we desire. By vigorous criticism and elimination of the undesirables they will get what they want, if only they will be guided by patient observation in their own and their friends' gardens throughout the year, rather than by occasional enthusiasm at a flower show or the credulous study of a catalogue. The improvement of the Rose as an exhibition flower is effected automatically; its improvement as a garden plant lies with the gardener.

WHITE ROSE.

DESIGNING A ROSE GARDEN.

A ROSE garden may often be made much more delightful by having some one point of interest besides the Roses, for nothing is more usual than to find that, except in the few weeks of its fullest bloom, the Rose garden is rather a dull place. There are several ways in which such an object of interest may be secured; either by a sundial or fountain, or a raised stone flower-bed, or a piece of ornamental sculpture in stone or lead, whether central or defining certain points of the circumference in prepared niches in the bounding hedge. In the case of the garden shown, this variation of interest is given by a tank for Water Lilies 20 feet across, giving good space for at least three kinds of beautiful Water Lilies. The low, flat kerb, which in an unbroken circle of this size would be a trifle monotonous, is varied on the four sides opposite the paths by a square projection, which gives width enough for the placing of four pots or small tubs of flowers in pairs. The four beds nearest the tank are also treated with a certain symmetry, and are planted with Lavender and China Rose, thus securing some permanence of effect and good clothing for all seasons, and so also joining in with the enduring and unaltering stonework of the tank. The small circles in the four diagonal angles are trained weeping Roses, of such a kind as the pretty pale pink Lady Godiva.

The large clumps have a middle mass of five plants of the fine rugosa hybrid Blanc Double de Coubert. This is chosen because of its handsome dark green foliage and for its way of forming a dense, bushy mass of solid character, quite different to the thinner habit of most Roses. The coloured Roses will come well in groups as shown, using four kinds in each clump. The names of the actual kinds are not given, because the choice will depend both on the character of the soil and climate and on the taste of the owner. But as a general suggestion as to colour arrangement, it would be well to have in the space B some good Rose of a deep pink or a clear rosy red such as Zephyrine Drouhin, in C a bright red, in D a white, and in E and F a light pink. The whole garden is much beautified by a complete edging of *Stachys lanata*. The flower-stems are cut out when half developed; then the plant at once spreads at the root and forms a silvery carpet. It is kept fairly even on the side next the turf, but runs freely into the bed where there is space between the Roses. This edging is not only most becoming to the Roses, but serves a useful purpose by defining the form of the design. Thorough preparation of the soil is, of course, essential for success, but this is dealt with fully elsewhere.

G. JERRELL.

A SUBURBAN ROSE GARDEN.

owner has widely used only one variety in a bed, so that a beautiful mass of one colour, instead of the too often bizarre effect, is obtained. For the purpose of providing flowers at those times when the Roses are more or less resting, the beds have been carpeted with Violas or Tufted Pansies, and in some instances Carnations are intermixed with the Rose bushes, the latter giving a wealth of fragrant flowers, cutting that time well surpassed by the Roses themselves. Well over two hundred different varieties are grown, those being selected principally for their freedom of flowering, good, distinct colours and even contour. These large-flowered kinds which naturally produce their blooms in clusters are vigorously disbudded, so that only the most promising bud is left on each stem. The result of this disbudding is that only large flowers of perfect contour are developed. Some of the best dwarf or semi-dwarf varieties in the beds are Duchesses (of Wellington) (soft yellow), Lady Hillington (pale shade of orange and buff), General MacArthur (coruscant), Mincie, K. A. C. (soft buff), Camoens (glowing rose), with yellow base, Cadme (faint pink), Earl of Warwick (flesh pink and rose), Etienne (Karl Druschki) (white), Grassan (Teplitz) (bright crimson), Gustave (Kaiser) (milk yellow, fading to cream), J. B. Clark (crimson scarlet), Lady Ashdown (rose pink), La Rosa (pale cream), Leon Rose (coral red, tinted orange), Mincie, Abel (Chateaux) (pink, suffused), Anne, Mincie, Leon Pann (silvery white), rose pink centre, Mrs. W. J. Grant (bright rose pink), Paul Fede (apricot, double rose), Richmond (glowing crimson), Sulphurea (bright sulphur yellow), Rayon d'Or (rich canary yellow), Pharisier (similar to Mincie), Leon Pann, Mincie, Melanc (Souper) (pale yellow, suffused amethyst), Antoine (Riviere) (pale cream), Mrs. Anna Ward

DURING recent years the cultivation of Roses in gardens situated in the suburbs of London has received a great impetus, and one of the most charming

instances that have come to our notice is at The Lodge, Surbiton Hill. Here Mr. William Hudson, the owner, has, in an area of less than an acre, formed a Rose garden of considerable beauty and interest. Until a few years ago the ground now occupied by Roses was a wilderness of overgrown fruit bushes, which have been disestablished in favour of the present inhabitants. The beds have been laid out with only so much formality as is given by their regular shapes and balanced disposition. There are no brick or stone paths, but the Roses make little oases of colour in their setting of green turf. Well-grown trees form a strong background, and in front of these the boundary fences have hidden their bareness behind a wealth of climbers of all sorts. In the borders in front of these climbers many choice herbaceous plants, particularly well-grown Delphiniums, Phloxes, Hollyhocks and tall Evening Primroses, luxuriant in bold masses, the whole forming a charming setting for the Rose garden proper.

In planting the Rose-beds the

A VIEW IN THE ROSE GARDEN AT THE LODGE, SURBITON HILL, SURREY.

A CLUSTER OF WHITE BLOOMS OF ROSA DUPONTII.

(Indian yellow, edged white), Mrs. George Shawyer (pale rose) and Prince de Bulgarie (pale rose, shaded apricot). At one side of the Rose garden is a large bed filled with that beautiful, but too often disappointing, variety, Juliet. This is a very vigorous-growing Rose, and Mr. Hudson has wisely allowed the long shoots to remain nearly their full length, pegging the tip of each to the ground. Nearly every lateral shoot produced from these is terminated by a large and fragrant bloom of bright rose colour, shaded old gold on the under side or reverse of the petals. This seems to be the best way to treat this variety for garden purposes.

When the fruit bushes were cleared away to make room for the Roses, a few old Apple trees were allowed to remain, and these now make excellent supports for many beautiful rambler and pillar Roses, such as Conrad F. Meyer, Blush Rambler, Lady Gay, Hiawatha, American Pillar, Tea Rambler and Dorothy Perkins. There must be many gardens where old Apple, Pear or Plum trees, no longer of value for their fruit, might be put to similar use. The Roses must, however, be planted well away from the roots of the trees, and the long shoots trained up among the branches.

In addition to these natural supports, a few rough Larch posts with portions of the lateral branches remaining have been let into the ground, and these support a number of good pillar Roses that are allowed to throw their vigorous shoots almost where they will, instead of, as is too often the case, being tied tightly to a plain, unbranched post. It is really surprising that rustic poles, old tree stumps, and rough Larch posts are not more often used for supporting Roses of rambling habit. Conrad F. Meyer has been especially good grown in this free and pleasing manner. In front of the house several fine weeping standard Roses have been planted, two of the best being Minnehaha and Jean Guichard. The illustration on the previous page represents a view in this garden at Surbiton, and gives some idea of the beautiful effect obtained by massing one variety in a bed, with pillars of ramblers forming a sort of open but harmonious background.

ROSE FORTUNE'S YELLOW AT LOCKINGE.

ALTHOUGH this beautiful Rose has been in cultivation for a great many years, it has not become so popular as its merits deserve. When well grown it is one of the most beautiful, as well as the most useful, Roses in cultivation. Although it may be grown quite successfully outdoors in a sheltered situation, it is perhaps more at home and of much greater value when grown in a cool house. My predecessor, the late Mr. W. Fyle, established it in three different structures in these gardens, and from these we cut large quantities of flowers all through the spring months. The earliest blooms are cut from two trees planted on either side of a rather low span-roofed house. The main stems are trained along the bottom of the rafters much in the same manner as a Vine. From these branches the young wood grows over the trellis and is trained about a foot apart.

It is while the growth of this wood is in progress that the strictest attention must be devoted to the general requirements of the plants, for the better this young growth is developed, the better will be the flowers, both in colour and substance. In passing I must say a word about the colour of this lovely Rose, as when seen at its best there are few Roses that can equal it in this respect. At Lockinge it assumes a beautiful apricot colour, which is more pronounced when the young flowering wood becomes thoroughly matured; therefore it follows that everything possible must be done to assist the perfect development of the young growths. The nature of the soil, too, undoubtedly has a deal to do with the colour of the flower, and as the natural soil here is very chalky, it would seem that this constituent is essential in bringing out the best colour in this particular Rose. The trees in this house are planted in a somewhat restricted, well-drained border, and during the growing season the roots receive copious supplies of water. The feeding takes the form of diluted drainings from the farmyard, and, as mentioned before, it is given principally when the young flowering growth is in course of development, and again while the flower-buds are developing. At the present time this growth is nearing completion, and for the next two or three months the trees must be induced to remain in a dormant condition. This is best brought about by keeping the house as cool as possible; therefore, when choosing the structure in which to grow them, one must be selected in which the temperature can be kept at about 40° during the time the Roses are resting. The flowering-time can, of course, be regulated by extending or shortening the season of rest; but, needless to say, the flowers which we get from the earliest house are not nearly so fine as those grown in the latest one.

We commence cutting the first blooms at the end of February from the first house; the second crop we get from a plant growing over the roof of a lorry conservatory; and the third and main crop from two large plants growing in a large, lofty house in which are stored specimen bedding plants during the winter. After flowering, the trees are pruned, which consists of cutting hard back all the old flowering wood. The young growths are very soon active, and from these the most promising are selected and trained over the trellis. During the growing season the trees must be gone over several times to remove superfluous weak

growth. After pruning, 2 inches or 3 inches of the surface soil is removed and replaced with fresh loam, old lime rubble and crushed bones, and later on, when the surface of the border is full of roots, a good top-dressing of well-decomposed farmyard manure is given, and this is thoroughly washed into the borders at once. The worst enemy of this Rose is mildew, which will quickly appear if the roots are allowed to become dry. During the growing season the trees are thoroughly syringed with clear water daily. All the trees here are growing on their own roots.

Lockinge Gardens, Wantage. E. HARRISS.

ROSE SPECIES OR WILD ROSES.

THEIR USE IN THE GARDEN.

THE beauty and consequent popularity of the large family of garden Roses is no doubt responsible for the rather meagre attention given to the species and botanical varieties. Though so neglected in our gardens to-day, quite a number of them are deserving of attention, even in small gardens. It may be for their pretty, daintily-coloured single flowers, their elegant foliage, attractive fruits in autumn and early winter, or their coloured stems and the striking character of the thorns. The Rose garden proper is not, of course, the place for the wild Roses, unless it be as a hedge to surround the garden, and possibly, if the environment is suitable, a few informal groups on the outskirts or approach to the garden. It is in the less formal parts of the pleasure grounds, the wild garden and open breaks in the woodland that they are seen and appreciated in their greatest beauty.

A considerable number of these bushes are self-supporting. Others, which include *Rosa arvensis*, the Ayrshire Rose, and *R. wichuriana*, are best when clothing a more or less steep bank, or scrambling over and perhaps hiding an unsightly fence. Yet another section, represented by the very

THE AYRSHIRE ROSE (*ROSA ARVENSIS*).

ROSA TOMENTOSA, A BRITISH SPECIES WITH PINK FLOWERS.

garden. *R. pyrenaica* is a dwarf form with long flask-shaped fruits, which ripen in August.

R. arvensis. This is a British species readily recognised by its long, slender, trailing stems. Popularly known as the Ayrshire Rose, the habit of the plant makes it very suitable for clothing banks and scrambling over old tree stumps. The white flowers, with a pretty tuft of yellow stamens in the centre, expand during June and July. The small, oval fruits are orange red in colour. Its elegant, graceful habit is noticeable in the illustration on page 510.

R. bracteata.—To grow the Macartney Rose successfully in all but the warmer parts of the country, the shelter of a wall is desirable. It is a native of China, and the large white flowers are delightfully fragrant and effectively displayed by the rich shining green leaves.

R. carolina.—The Swamp Rose of North America, this species may be grown successfully in damp situations by the lake-side and stream. It forms a large bush some 6 feet in height, with

THE MUSK ROSE (ROSA MOSCHATA).

clusters of pretty pink flowers produced from June to August.

R. cinnamomea.—This is a pink May-flowering Rose native of Europe and North Asia. It forms a large bush 7 feet to 8 feet high, with conspicuous dark red, round fruits in autumn.

R. Dupontii.—A pretty bush 4 feet to 6 feet high, with clusters of blooms, well shown in the illustration. The long, flask-shaped fruits are orange red in colour.

R. Hugonis.—This species is of comparatively recent introduction from China. Growing 6 feet or more in height, the rich yellow blooms, 2 inches across, are freely borne during May and early June. When not in flower, the elegant, fern-like foliage attracts attention. *R. Hugonis* is adapted for a bed in the pleasure grounds or for massing in the shrubbery border.

R. indica, the Monthly Rose, seems never out of flower from early summer till spoilt by frosts in late autumn. It is perhaps best known as the parent of the dwarf tree-flowering Tea and China Roses. The type has rosy red blooms while a

dainty dwarf-growing variety named *sanguinea* has semi-double, rich crimson flowers and reddish leaves. The latter is a gem for the rock garden. *Viridiflora* or *monstrosa*, the green-flowered Rose, is grown by some as a novelty.

R. lævigata, the Cherokee Rose, should be planted at the foot of a warm south wall. The large white, single blooms, with a setting of the shining green foliage, cannot fail to appeal to lovers of Nature. A variety, *Anemone*, with silvery pink flowers, is delightful towards the end of May.

R. lutea, the Austrian Briar, flowers in May. The type has single, yellow flowers, and a form with attractive reddish brown flowers is named Austrian Copper. Perhaps the most useful and attractive of all is *Harrison*, a semi-double yellow variety which makes a splendid hedge or specimen bed 4 feet to 5 feet high.

R. macrantha is a delightful single Rose with large bluish white or flesh-tinted petals. It is supposed to be a hybrid between *R. canina* and *R. gallica*, and makes a more bushy specimen.

R. moschata, the Musk Rose, is very vigorous in habit, climbing up lofty trees and hanging in festoons from the branches, clothing arbours or scrambling over old outbuildings. The large panicles of fragrant white blooms are at their best at the end of June and during July. The variety *Brunoni* is a glaucous-leaved variety, and *Pissardi* is a semi-double, perpetual-flowering variety not so tall and vigorous in growth.

R. rubiginosa, the Sweet Briar, is well known by reason of its fragrant leaves. It makes a splendid hedge Rose, and is attractive when in flower and laden with fruits in autumn. As the parent of the Penzance Briars, it has resulted in the introduction of numerous delightful additions to our strong-growing single Roses.

R. rugosa, the Japanese Rose, makes a splendid hedge or large bed in the pleasure grounds. The large rosy red blooms and handsome red fruits are freely produced. There are numerous varieties

ROSA SOULIEANA, FROM CHINA.

vigorous *R. moschata*, will, with a little encouragement in the early stages, scramble up trees to a height of 25 feet or more, and make a most effective picture when in flower. A few of the most useful for prominent beds in the pleasure grounds are *R. Hugonis*, *R. lutea*, *R. indica*, the Scotch Rose, *R. spinosissima* and varieties, *R. Moysesii*, *R. rugosa*, *R. nitida* and *R. sericea pteracantha*.

The wild Roses will thrive in most soils; but in poor and sandy, incorporate plenty of old decayed manure, cow-manure for preference, previous to planting, an occasional mulching with manure being also very beneficial. Seeds and cuttings form ready and easy methods of propagation. As, however, the single Roses hybridise very readily unless the fruits are collected from isolated bushes, it is safer to propagate by means of cuttings. No pruning of the Rose species is necessary, but an occasional thinning of the shoots is desirable after flowering, the older wood being cut out, if possible, in some instances down to the ground, which will generally have the effect of inducing vigorous young shoots to push up from the base. There are probably about a hundred distinct species, and an equal number or more botanical varieties. To contain anything like a representative collection of these beautiful single Roses, the garden must obviously be a large one. There are, however, few gardens in which space cannot be found for some of the best, a selection of these being given.

Rosa acicularis.—This Siberian Rose forms a shapely bush 6 feet to 7 feet in height. The bright rosy pink flowers appear towards the end of May, and are followed in autumn by shiny, Pear-shaped, waxy red fruits. The foliage is attractive in summer, and in winter the reddish colour of the twigs is noticeable.

R. alpina.—The single, rosy red flowers of the Alpine Rose are welcome in May, as also are the red hips in autumn. It is an European species, and varies considerably in height, a dwarf, free-fruited variety being very useful in the rock

or hybrids of the rugosa Rose in cultivation with single and semi-double blooms, notably the large white-flowered *Blanche Double de Coubert* and the fragrant, though quite double, *Conrad F. Meyer*.

R. sericea is one of the most distinct single Roses with its four-petalled, pure white flowers. It is an excellent Rose to plant as a specimen bush, growing 6 feet to 8 feet high and as much through, with elegant, Fern-like foliage. The variety *pteraantha* is a most distinct plant, with huge red thorns thickly clothing the branches.

R. soulieana is a tall, vigorous-growing bush with very beautiful glaucous foliage, spiny shoots and long sprays of white flowers, followed in the autumn with orange red fruits. A native of China.

R. spinosissima, the Scotch Rose, grows from 2 feet to 3 feet high. There are numerous varieties with white, yellow, pink and blush single and semi-double flowers. *Altaica* is a tall-growing variety 3 feet to 4 feet high, with white flowers.

R. tomentosa is a European species including Britain. The rose pink flowers are borne on bushes some 5 feet to 6 feet high during June and July. In autumn the round, red, bottle-necked fruits are prominent.

R. wichuraiana.—The introduction of this late-flowering Japanese Rose has caused quite a revolution among climbing or rambling Roses, and it begins to make one wonder what our gardens looked like before the coming of *Dorothy Perkins*, *Hiawatha*, *American Pillar* and numerous others. Being an ever-green species, *R. wichuraiana* is very useful for clothing bare banks and tree stumps. The dainty white blooms, with a tinge of yellow stamens in the centre, are at their best during August and September. A. O.

HINTS ON STANDARD ROSES.

IN order to have first-rate standard Roses it is necessary to commence with good Briar stocks. I prefer to collect my own Briars from the hedgerows in the autumn,

but, needless to say, it is not everyone who would care to take up this pursuit. Where choice

is possible, I prefer two year old shoots for stocks, and, failing them, three year old shoots, but growths in the first year are generally to be avoided, as the wood is often soft and pithy. Stocks without roots at all will grow it grubbed out below the surface of the soil, but these should only be used when short. That there is an element of risk in leaving the collecting of Briars to the uninitiated is seen by the amusing incident related by the late Rev. A. Foster-Melhar, Rector of Sproughton, Suffolk: "When I was ill one winter I was pleased to hear that a parishioner had brought me a nice lot of stocks at a reasonable price. One of the first acts of my convalescence was to inspect their quality. And alas! not only were the

majority practically useless, from chops and other injuries, but a third of the whole were not Rose stocks, but Blackberries!" Of course, it is not necessary to collect Briars from the hedgerows, as these may be raised in any garden or, better still, purchased already worked and made into standard Roses from the nurseryman, and this is unquestionably the best course for the beginner to pursue.

Standard Roses are sometimes injured by wind and frosts, and, where possible, they should be sheltered from the north and east. Shelter is also advisable from the south-west, as it is from this quarter that our strong winds blow, which may cause the stakes to break off near to the soil-level. In such cases

A BED OF STANDARDS OF ROSE FLORENCE PEMBERTON, WITH VIOLA WHITE SWAN AS A CARPET.

the old stumps should be drawn from the earth and the stakes renewed without delay. Buildings form the best shelter, and that is one reason why standard Roses are often a great success near the approach to the house.

Generally speaking, Hybrid Teas make the best standards. The Hybrid Perpetuals are often too vigorous, and are seen at their best when pegged down in beds. Teas, however, make good standards and often produce the finest exhibition blooms. The varieties *Hugh Dickson*, *Mme. Abel Chatenay*, *Lady Ashtown* and *A. R. Goodwin* make admirable standards, but a variety that has excelled itself for profusion of bloom this year is undoubtedly *Florence Pemberton*, the subject of the illustration.

The photograph from which the illustration was prepared was taken in mid-June, although at the time of writing (October 2) there is even a greater abundance of bloom to be seen on the same trees. It is a much-debated point as to whether other plants should be allowed a place in the Rose garden. But for standard Roses, at least, a low carpet of some other flowering plant will do much towards hiding the surface soil and the bare legs of the standards. For this purpose nothing is better than the *Viola*, although *Mignonette* is likewise very suitable. If *Violas* are used, then whites or pale yellows such as *White Swan* and *Primrose Daine* will be more in keeping with the Rose garden; the mauve and purple shades should be excluded.

Weeping standards are much in favour now, and deservedly so, for it would be hard to conceive a more lovely object on a lawn than, say, a weeping standard of *Delight*, with drooping sprays wreathed in bloom down to the level of the lawn. Many varieties, notably *Alberic Barbier*, *Hiawatha*, and *Shower of Gold*, may be grown in this way, while *Blush Rambler*, *Dorothy Perkins*, *Lady Gay*, *Hélène*, *Grüss an Teplitz* and *Mme. A. Carrière* are just a few of the free-headed standards that look well in isolated positions on lawns. C.

COLOURED PLATE.

PLATE 1478.

SINGLE AND SEMI-DOUBLE ROSES.

DOUBTLESS many living rosarians can recall the time when single and semi-double Roses were held in very poor esteem, and to have awarded them gold medals would have brought down upon the heads of the judges considerable disapproval. This has all been changed, and to-day we find a growing regard for the exquisite single and semi-double Roses, especially those of almost ever-blooming quality, that we trust will long remain.

It was thought when Messrs. Alexander Dickson and Sons gave us *Irish Elegance* in 1905 that the climax of beautiful colouring had been attained; but this celebrated firm have now produced *Irish Fireflame*, one of the subjects of our coloured plate, which, we venture to say, will soon be in every garden in the land. One could obtain some idea of its beauty when it was staged for the gold medal and secured it at Southampton last year, but to see it growing in its home at Newtownards, as we have done, has made our task of writing about its charms one of real pleasure. At Newtownards we saw row after row of it growing in the greatest luxuriance, appealing to us not alone by its wonderful colour, but also by the beauty of growth, foliage and habit.

There has been some correspondence in our columns regarding the free blooming of *Irish Elegance*. We may say here that this grand Rose

TWO NEW ROSES

Single: Irish Fireflame
Double: Queen Mary.

is always in bloom with us upon practically unpruned bushes, some as much as 4 feet through, others 7 feet to 8 feet high on east walls, all treated alike, that is, a sparing of the pruning-knife. Irish Fireflame, growing like this, will be one of our very best garden Roses, and will doubtless be planted in quantities; for where is there any more exquisite or elegant Rose for decorating a table?

We shall always retain a vivid recollection of the first time Messrs. Dickson exhibited Queen Mary, the second subject of our coloured plate. This was at the Festival of Empire, Crystal Palace, on which occasion it was awarded the silver cup as the best seedling Rose shown. This was soon

perpetual-flowering quality, and here they score largely over the single and semi-double species that are not perpetual. We feel sure there is a great future for such Roses, and many of the novelties not yet in commerce, which we saw at Newtownards, Belmont and Portadown during a recent visit to Ireland, displayed such a remarkable shrub-like habit that we thought then what perfect-flowering shrubs they will make and how our gardens will be enriched by their introduction.

Our advice to raisers is to strive after the glowing tints that are absent among flowering shrubs, and also for the hardiness and the true perpetual-blooming of the old common Monthly Rose, and

vigorous and free-flowering. It is, moreover, perfectly hardy. The flowers are pure white, well formed and very fragrant. I myself can claim no credit for the surprising growth this variety has made here, for beyond, every few years, cutting out some of the dead wood at the back and nailing up the more rampant shoots, it has received no cultural care whatever. The original plant, which covers two-thirds of the space on the front of the house and a large space at the side as well—which is not seen in the illustration—I found growing on the left-hand side of the porch when I first came to Rosebank twenty-eight years ago. Judging by the size of the stems then, I should say it must have been there from fifteen

ROSE BENNETT'S SEEDLING ON THE FRONT OF ROSEBANK, BERKHAMSTED, THE RESIDENCE OF MR. T. MAWLEY, SECRETARY OF THE NATIONAL ROSE SOCIETY.

after the advent of Juliet, and we could not help remarking that there was in its wonderful colouring something that recalled that wonderful Rose. The remarkable colouring of canary yellow and carmine, the latter shade being crayoned upon the yellow and not infused, makes this Rose a gem of rare beauty, and Messrs. Dickson could not have chosen a more lovely Rose to bear the name of our gracious Queen. The growth is vigorous, and, as we saw it growing, its habit and bronzed apple green wood gave one the impression that we had here a Rose of real merit, and one of which there could be no cavilling as to the correct estimation it has obtained at the hands of the National Rose Society when they awarded it the gold medal in July last.

The great merit of the two Roses named above, apart from their colouring, is in their practically

we can accord them in the name of our readers a very generous welcome.

ROSE BENNETT'S SEEDLING.

THE Rose growing over the north-west front of my house at Berkhamsted is an old Avrshire Rose known as Bennett's Seedling, and was so-called after the gardener who raised it. It is also known as thoresbyana, because it first saw the light in the gardens of Thoresby Hall, Lincolnshire. Even at the present day it would be difficult to find any climbing Rose possessing so many good qualities. As will be seen by the illustration above, it is remarkably

to twenty years. The plant on the right-hand side of the porch was put in by me about twelve years ago, and, considering the time it has been there, has done equally well. This part of the front was covered with a Wistaria when I came to Rosebank, but as it flowered, as a rule, so sparsely, the Rose on that side was allowed to do its worst, and, as will be seen, has at last succeeded in completely smothering the Wistaria.

I can truly say I have no other Rose in my garden which behaves itself so consistently well, or gives so little trouble or so much pleasure. It is, as I said before, perfectly hardy; in fact, whatever the previous winter, spring or early summer may have been, it year after year without fail presents the same sheet of pure white blooms when in flower. It is never troubled with any insect or fungoid pest, and notwithstanding drought,

frost, cold winds or other enemies, which every now and then so seriously affect the well-being of other Roses, always comes up smiling at the flowering-time.

But there is a reverse side to every picture, however lovely. In this case there is the sad fact which I have intentionally left till the last, and that is it only flowers once in the year, and then only for a few weeks, which in these days of continuous-flowering Roses will, no doubt, be regarded as a drawback. Still, Bennett's Seedling is a climbing Rose well worth growing for many reasons, and there will, no doubt, occur to your readers many positions where such an adaptable variety would prove invaluable. If not ever-flowering

Wagram. To some the perfume is delightful; to others the odour is not nice.

Then, again, the temperature of the atmosphere has a good deal to do with the value of the perfume-giving quality that any particular flower gives off. If a census of opinions the world over was taken as to the most delicately-perfumed Rose, surely that old variety, La France, would win easily—and in my humble opinion there is no Rose that can equal this variety. [We prefer Mrs. John Laing.—Ed.] Why do the dark red Roses easily outshine any others in perfume? This is answered: Because most of them have coursing through their veins the blood of the Old Damask. Why, then, is it that certain Roses, new productions due to the hybridiser (who, maybe, has used a dark Rose

great list; indeed, they are nearly all sweet-scented. Who can find better Roses than Alfred Colomb, Hugh Dickson, W. E. Lippiatt, Marie Baumann, *Senateur Vaisse*, Ulrich Brunner, George Dickson and Laurent Carle?

Should the reader require a different perfumed Rose to any I have mentioned, he must turn to the pure Teas. Why are they called Teas? Is it because they are scented like Tea, or is it because their first parents came from China? The scent of Tea Roses is, in my opinion, an acquired one; it grows on one like tobacco. Marie van Houtte, Mme. Hoste, *Maréchal Niel*, Mrs. Edward Mawley and Alexander Hill Gray are a few of those which possess the highest degree of Tea Rose perfume. Among climbing Roses, one has but to think of *François Juranville*, *Gerbe Rose*, Bennett's Seedling, and many others that are a great acquisition over a summer-house. Then, again, one must not forget the Hybrid Sweet Briars which the late Lord Penzance has bound inseparably with his name. These plants are at their best during an early summer evening after a shower of rain. There can be no gainsaying the fact that there are a great many people who, unless a Rose has a definite perfume, will have nothing to do with it. This is not fair. Indeed, they go so far as to say that it should have been "drowned when a pup." Do they realise that this same Rose, scentless I grant you, may some day be the parent of a flower outrivalling even La France? Where would Fran Karl Druschki stand if it could emit the odours of Horace Vernet or Charles Lefebvre? No; let us be thankful that we have Roses both scented and unscented. The one enhances the other, and makes us all the more conscious of their merits.

O'DONEL BROWNE, M.D.

Gortnagrenn, Naas, County Kildare.

A BASKET OF ROSE CHERRY PAGE, A NEW DECORATIVE VARIETY OF RARE BEAUTY AND FRAGRANCE.

in the summer and autumn, it is in most winters evergreen.

EDWARD MAWLEY.

ON SCENTED ROSES.

WHY is the Rose always considered the premier flower? Surely the answer is because it has more good qualities than any other variety, and of these good qualities that of perfume must rank pre-eminent. To my mind there are other flowers whose perfumes are delicious in moderation, but when cut and left in a room one soon experiences a sense of heaviness and a tendency to headache. The Rose cannot be accused of this habit. In a Rose there is a subtle blending of odours such as you do not get in any other flower, and this is well exemplified when different people are asked their opinions upon a certain flower, e.g., Mme.

in his cult), have no perfume? There I leave you. He, in his endeavours to cross one variety with another, has transgressed some law which Nature alone knows. This last remark may seem strange to some, but it is an undoubted fact that most of the modern Roses are sadly deficient in perfume. Frau Karl Druschki, William Shean, Mrs. Theodore Roosevelt and Mildred Grant are practically scentless, yet, withal, they are glorious flowers.

Now, if we turn our minds to those sweetly-scented varieties, we shall find that the list is a very large one, and we can find nearly every colour therein in flowers to suit our eyes as well as our olfactory lobes. Of the pink varieties we have Mrs. John Laing, Countess of Caledon, Gustav Grunerwald, Dr. O'Donel Browne, Mme. Gabriel Luizet and Gladys Harkness—all perfectly-perfumed Roses and all good, honest growers. The variety named after myself, I consider, has a grand perfume, and is a good doer in every way. Sometimes I wish I were the flower! Of crimson we have a

ROSE CHERRY PAGE.

THERE was a basket of Roses exhibited at the National Rose Show in July last which attracted considerable attention, and we have the pleasure to illustrate this basket in our present issue. The variety was named Cherry Page, after the daughter of our able correspondent, Mr. Courtenay J. Page, who is also a prominent member of the Council of the National Rose Society. The Rose belongs to the decorative section of the Hybrid Teas. Perhaps we should be correct in saying that this variety is one of the most remarkable coloured Hybrid Teas we have met with for a long time, and it is a most difficult task to define its true colouring. Mr. Walter Easlea, its raiser, informs us that there is no variety among his large collection of Roses at Eastwood that calls forth so much admiration, especially from lady visitors, as Cherry Page, and we are pleased to know he is placing it on the market next spring. The colour is a glowing orange cerise, with shading of vermilion towards the edges of the petals, and the base of the petals is a beautiful daffodil yellow. The growth is very strong and erect, sending up fine, rich ruby coloured shoots and foliage that blend so well with the lovely flowers. The Rose is semi-double, with huge petals, and during very sunny weather the flowers expand to a width of 5 inches, revealing the golden centre and a wealth of golden stamens. For table decoration we believe Cherry Page has a great future, and feel sure it will take a leading place among Roses planted for massing and general garden decoration.

ROSES FOR BEDDING.

THE best varieties of Roses for exhibition are not always the best for garden decoration. The former concentrate all their energies on producing a few (sometimes very few) choice, well-finished flowers, while the varieties suitable for the latter purpose are those which produce a quantity of bloom throughout the season, that is, from June to the end of October, and, when the season is favourable, right up to Christmas. For instance, we would never think of planting such varieties as Dean Hole, William Sheran, Bessie Brown, Mildred Grant, Albatross, Maman Cochet and Mrs. J. Lang for producing quantities of bloom, but rather such varieties as Caroline Testout, La France and its sports, Mme. Abel Chateau, Prince de Bulgarie, Joseph Hill, General Macarthur (probably the best red Hybrid Tea we have), Fochennant Chantre, Richmond, Liberty, Duchess of Wellington, Antoinette Rivoyre, Grüss an Teplitz and Frau Karl Druschki.

In small beds one variety only should be planted, but in beds that will take from two dozen upwards, two or three varieties, preferably of one colour, should be used. In this way a more continuous display may be looked for, as the chances are that one or other of the varieties will produce blooms right through the season. The above illustration shows a bed planted in this way; Caroline Testout and La France planted alternately with ramblers down the centre, and bordered with White Pet. The other illustration depicts borders

LA FRANCE AND CAROLINE TESTOUT PLANTED ALTERNATELY WITH RAMBLERS INTERVENING.

of light-coloured varieties, which bloom continuously right away through the season and were producing last November first-class blooms.

The dainty little China Roses, too, lend themselves admirably for the purpose of producing a continuous and pleasing effect, and a mixture of Comtesse du Cayla, Chin Chin China, Mme. Engle, Resal and Laurette Messimy (the last two in the centre of the bed), carpeted with some pale, contrasting coloured Viola, will delight the eye for months for a fraction of the trouble necessary to keep ordinary bedding plants in good trim, and the wonder is that we still continue to use the latter as we do when we can get such a variety of pleasing combinations with the sweet-smelling and varied coloured Roses.

The colours of many of our hardy herbaceous plants associate well with those of Roses, but care must be taken that no "self-assertive" colours, but only the quiet soft ones are used. Scarlet, or bright red especially, should never be planted where they can be seen at the same time as the Roses.

The distance apart for planting must be regulated with an eye to the future, the weaker-growing ones, especially if no "carpet" is intended being placed rather closely together, only allowing sufficient space for the hoe to be worked, while the stronger varieties should be allowed more room and pruned rather sparingly. J. B. Clark requires quite 6 square feet for each plant, Grüss an Teplitz (one of our sweetest Roses) the same, and neither of them should be pruned beyond taking out the old wood and slightly shortening back the young. The same may be said of most of the strong, vigorous varieties. R. B. L.

ROSES TO GROW AS LARGE SHRUBS.

IN the search for fresh effects in the Rose garden, the use of the larger bush or shrub Roses must not be overlooked. We know how in the last few years the introduction of ramblers as weeping standards has changed the aspect of Rose gardening. Similarly, by the use of the larger shrub Roses we may obtain effects of a wider colour range and more varied habit. Even some of the wickiana Roses used as standards are perhaps more successful if used as bushes. Kinds such as Paul Transon, Ariel, Robert Craig and others with their upright growth make big, bold pillars; and Gerbe Rose is, with its glossy foliage, an almost ideal bush, often blooming again in autumn. It is to the perpetual-flowering kinds we must look most, for the older kinds, such as Anderson, the Damasks and the Austrian Brides, pretty in their way, are not things of beauty in the autumn,

BORDERS OF LIGHT-COLOURED ROSES AT WOOD HALL, DULWICH.

being only summer-flowering. The Austrians, however, have recently given us autumn-flowering hybrids which are well suited for this purpose. Through Soleil d'Or have been obtained Juliet, the beautiful and distinct Beauté de Lyon, and Louis Barbier, and doubtless there are others to follow. A tall-growing Rayon d'Or would be an achievement indeed. The rugosas, too, are autumn-blooming. Conrad F. Meyer is an almost perfect Rose grown in this way, and Blanc Double de Coubert and atropurpurea are hardly less suitable.

By entering into the large and comprehensive class of Hybrid Teas we also find some which are shrub kinds. Grüss an Tepnitz with its cascades of flower, its offspring Hugh Dickson, and J. B. Clark form a trio of similar foliage and habit. There is a Rose, Mme. Wagram C. de Turenne, included in this class which is essentially a Bourbon, derived from Souvenir de la Malmaison and crossed, it is said, with a Dijon Tea—let us hope with the old Gloire de Dijon, for it would be pleasant to know of the successful marriage of two such old favourites. It is most distinct in foliage and general appearance, and flowers well into the autumn. Allusion to the Dijons reminds us of Bouquet d'Or and Mme. Bérard, both making big bushes; and the same may be said of William Allen Richardson.

It is to the Noisettes and other Musk hybrids, in fact, that we must look in the future, for it is among these that the desired qualities lie. The white and pink forms of Pissardi are both shrub Roses, and so are Aimée Vibert and Alister Stella Gray. All these, however, are well known, but there are some later introductions which can be instanced as distinct advances in this direction. Trier, the first of these, was followed by Adrian Riverschon, with large trusses of single flowers, rose, with white eye, now (on September 12) in fullest bloom and about four feet high. It is a new colour in the Musks, and well worthy of cultivation in the bush form.

Much praise must be given to Mr. Pemberton's beautiful novelties Daphne, Danæ and Moonlight, which received such high awards from the National Rose Society. The last two, so well exhibited at the recent autumn Rose show, are destined to a prominent place in the Rose garden, and I think their true place is here among the shrub Roses.

I will conclude the list by naming Zephyrme Drouhin as distinct and beautiful grown in this way. Standing singly upon lawns and extended into shrubberies, these Roses have a charm peculiarly their own, while planted in the wild garden they, with their masses of bloom, and in some cases berries, enliven and enhance the scene, especially when in proximity to autumn foliage and surroundings.

G. L. PAUL.

THE BEST ROSES FOR PERGOLAS.

IN making a selection of the most suitable Roses for a pergola, I would like to confine the list to varieties of the wichuraiana type, because they possess all the attributes that go to make a successful pergola display. The objection to this method of classification is that this section does not flower until the middle of July, and oftentimes later, whereas some of the varieties in other sections open their blossoms quite early in the season—for example, Carmine Pillar

without a late-flowering variety. I will, then, as briefly as possible, enumerate two dozen of the most suitable, leaving planters to make their own selection of a few or many, giving the points of excellence of each as they open in order.

Carmine Pillar (Paul and Son, 1896) produces its large, single flowers in profusion; rose carmine.

Brunonis, the Himalayan Briar, has pure white, single flowers with yellow stamens, produced in the greatest profusion quite early, giving a most pleasing perfume.

Aglaia (Lambert and Reiter, 1896) is often called the Yellow Rambler. In colour it is pale yellow, with a strong Tea perfume. Its shell-shaped petals last a long time. This Rose does not come readily into flower in quantity until it becomes established, and often, owing to mistakes in pruning, it has been condemned as a shy-flowering variety; but I can assure my readers it is not so when properly treated, allowing the long, vigorous shoots to remain unpruned.

Claire Jacquier (Bernaix, 1888), minked yellow, very free, sweetly perfumed and with deep green foliage.

Mme. Alfred Carrière (Schwartz, 1879).—The buds are delicate pink, the fully-expanded blooms pure white.

Crimson Rambler (Turner, 1893) is still unequalled for brilliancy of colouring and freedom of flowering; but, unfortunately, it is so susceptible to mildew, except when great care is exercised in its cultivation.

Mrs. F. W. Flight (Flight, 1905), rose pink with white centre; semi-double. The trusses are produced in huge clusters. This Rose probably lasts longer in flower than any other; it is of sturdy growth.

Tea Rambler (Paul and Son, 1902), coppery pink, with a salmon flush.

Blush Rambler (B. R. Cant and Sons, 1903) is of extra strong growth, producing its huge trusses of rich blush, white-centred flowers freely.

American Pillar (Conrad, 1909).—If it were possible to say which is the most showy Rose in the whole section of climbing varieties, I should name this. In growth it is very vigorous, single shoots running up as much as 10 feet in one season, which the following year give huge crops of bloom, as many as twenty flowers in a cluster. In colour crimson, with a pure white eye.

Paul's Single White (G. Paul and Son) is a vigorous-growing, free-flowering variety, giving its pure white, single flowers in abundance.

Flame (Turner, 1912), bright salmon pink, produced in huge clusters; strong, vigorous growth.

Debutante (Walsh, 1903) produces its long racemes of rosy pink blooms freely, and owing to the manner in which they droop, are specially suited for a pergola.

THE NEW GOLD MEDAL ROSE MRS. JAMES LYNAS, RAISED BY MESSRS. HUGH DICKSON, LIMITED. COLOUR, RICH BLUSH PINK.

in June—and thus we get a longer and more interesting flowering period. With the object, then, of catering for all periods of flowering, I make the selection more of a general character. Although Roses have increased enormously of late, we are still without a good yellow climber after Aglaia and Claire Jacquier are over. I am often asked to name a yellow to flower at the same time as Dorothy Perkins. I confess I do not know of one that I can recommend. Of white-flowered varieties, too, there is a dearth at the same period. If it were not for White Dorothy, we should be quite

Evangeline (Walsh, 1907) is a hybrid wichurana, growing freely and giving huge quantities of its white-centred, pink-tipped single flowers.

Francois Juranville (Barbier, 1906) gives large flowers often singly as well as in clusters, and is continuous in flowering; bright salmon pink with an orange base.

Sweetheart (M. H. Walsh, 1903) is quite the best of white climbers of the wichurana type. In bud the colour is pale pink, changing to pure white as the flowers expand. The blooms are quite double and sweetly perfumed.

Minnehaha (Walsh, 1905), dark rose, quite double, sweetly scented. The blooms are somewhat widely set apart, which gives the plant a distinct character.

Dorothy Perkins (Perkins, 1902) is still one of the most suitable for pergolas, giving its soft light pink flowers in great abundance.

Lady Gay (Walsh, 1903) is so often confused with Dorothy Perkins that many people have come to regard them as being identical, which they are not. Lady Gay has cherry pink flowers much larger than Dorothy Perkins, while the trusses, too, are larger and the flowers more widely set apart.

Dorothy Dennison (Dennison, 1909) is identical with Christian Curle and Lady Godiva. It is a shell pink sport from Dorothy Perkins, having all the desirable characteristics of its parent in growth and freedom of flower.

Excelsa (Walsh, 1909) is best described as a scarlet Dorothy Perkins. In colour it is the most brilliant of all, growing freely and blooming in the same manner.

Hiawatha (Walsh, 1905) is a brilliant scarlet, single-flowered variety, producing its lasting flowers in freedom.

Coronation (Furner, 1912), bright crimson, shaded scarlet, splashed with small white streaks; of free growth and flowering.

White Dorothy (Paul and Son and B. R. Cant, 1908) is a white sport from Dorothy Perkins. Unfortunately, the colour is not pure, having here and there splashes of pink. In any case it is desirable, flowering as it does quite late in the season.

The remarks on cultivation will be necessarily brief. Deeply-trenched, heavily-manured, stiff soil fully a month before planting to allow the soil to settle down to near its natural level is all that is required in preparation. Planting is best done at the end of October, as fresh roots will then be made in the autumn, thus giving the plants a good start in the spring.

Pruning the first year is important. Planters like to have a full crop of flowers the first season. This, or a partial crop, can be secured from some varieties; but it is not wise to allow the plants to do so, as the growth made then is not so strong as is desirable to cover the pergola quickly, which is the object to aim at. It is wise, then, under these conditions to cut the plants down in the spring to within a foot or so of the soil, to induce the growth of strong basal shoots, which will give a full flower crop the next year. Another plan to treat plants with several shoots is to cut half of them severely and allow the remainder to give flowers at once, simply removing the top of each shoot so retained. The second year and afterwards cut away all small growth that has given a flower crop, if abundance of new shoots from the base has been made. This pruning is best done

directly the flowers have faded, thus giving more light and air to the remaining shoots.

Feeding the plants to maintain vigorous growth is important. Sometimes manure cannot easily be added to the soil. In that case liquid manure applied freely during the growing season is beneficial, and so are sprinklings of soot applied to the surface during showery weather, or any of the artificial manures advertised applied judiciously. Green fly is quite the greatest pest Roses have to contend with in the spring. If the plants become infested with this aphid, the growth is checked and the season's flower crop spoilt. Prompt measures should be taken directly the first fly appears. I have found nothing better than McDougall's "Katakilla," which is so simple of application and effective.

In forming a pergola, so many persons make the mistake of having it too low; 7 feet I recently saw one. This height does not allow of the flower-sprays hanging down in comfort, which is the charm of all pergolas and the natural tendency of climbing Roses, especially of the wichurana type. No pergola to be satisfactory should be less than 8 feet high, the same width, and that distance from post to post.

Swanmore.

E. MOLYNEUX.

IN A HAMPSHIRE GARDEN.

SOME OF THE NEWER ROSES.

THE year 1913 will not go down to posterity as an *annus mirabilis* in Rose annals, for the Clerk of the Weather, that presiding genius of the feast, has not been too kind, and has distributed his favours with somewhat too partial a hand to please all or even the majority of us; and while some of my friends have called it a dry summer, others complain that there has not been enough sun, and that mildew has been very prevalent; but the more favoured ones have not had much cause to complain, and the South and East of England have had a good Rose year. At any rate, in this neighbourhood we have had, and are still having, one of the finest summers I remember. There have been no extremes of heat. On the contrary, though fine, it has been a cool summer, and Roses have benefited accordingly. As I write, in the last days of September, not only are there plenty of flowers, but the promise of many more to come is even more apparent, and only Jack Frost is likely to prevent their coming to bloom and brighten the November and December days.

This is, after all, *the* feature of the newer Roses. Much as the hybridist has improved colour, form and scent, his greatest advance has been in evolving a type of Rose that combines all these three most desirable attributes with an enhanced length of flowering period, almost in some cases continuous, so that the plant carries flowers all the time from May until December. Although I have headed this article "In a Hampshire Garden," I shall not absolutely confine myself to only those Roses that are growing therein; for new Roses are now so numerous that even our largest trade growers are hard put to it to find room for them, and it is obvious my small garden, of less than half an acre, cannot contain more than a selection of the best, so that I shall find myself referring in these notes to Roses seen in the tented field, the lofty hall, the nursery

grounds of our great Rose-growers, and where, I venture to think, they are at their best—in the gardens of those who love them. Still, I am firmly convinced that it is but little one can know of Roses if you have not grown them, and I shall always indicate this absence of the soundest basis on my part. Another reason why I have headed these notes "In a Hampshire Garden" is that I do not want them to be misleading, and if I am led to recommend a Rose because of its behaviour with me, it does not necessarily follow it will behave in the same fashion in the North of England. It is only another illustration of the truth of the saying that the best knowledge is that gained by one's own experience. The great secret of all successful gardening is to find out what you can grow, and grow it. We are all constituted much on the same plan, but our elevations are varied; and while one garden enthusiast seems to turn his garden into a kind of hospital where all the inmates are patients, each undergoing a course of treatment and mostly barely existing, another, equally enthusiastic, will not have anything to do with a delicate subject. If it is not robust and enjoying its life to the full, seemingly making the very best of what the gods provide, out it comes, to make room for something that will. In my own case, if I have any leanings, it is towards the latter of these two, and where one's space is limited it seems to me that one gets more satisfaction; but it is not so with everyone. They prefer a tender plant that must be coddled and protected to one that will look after itself and cause no anxiety. That is, perhaps, one reason why I grew but few Tea Roses till I came South. Here they can take care of themselves and get very little different treatment from the rest of the Roses; but a Tea Rose that is healthy and robust and strong down here is a very different subject further North.

Perhaps before setting down in detail the descriptions of the newer Roses, it might be advisable to take a general survey of the Roses of the year and just mention a few that have seemed to stand out partly from their own intrinsic merits, or from the climatic conditions at the moment having suited them. It is not necessary to divide them into classes. I will mention them as they occur to me. It is a very long time since a Rose distributed one year proceeds in the next season to occupy such a prominent position as George Dickson has this year. It is undoubtedly entitled to be called the finest exhibition Rose of its colour, and among exhibitors that are keen, few would care to be without it. Not only the raisers, Messrs. Alex. Dickson and Sons of Newtownards, but at one time or another all the big growers seem to have been able to produce fine flowers of this variety, and those amateurs who were fortunate enough to secure plants or buds of it last season have been able to show very fine flowers throughout the year. Most of the flowers shown have actually come from maidens, but it has been quite good with me on cut-backs; it is a good grower, with fine constitution, and not subject to mildew. I do not mean to say it is mildew-proof, but it has been practically free from mildew with me. It has stood out, so that if 1913 could be labelled, as Rose years sometimes are labelled, with the name of any particular Rose, I think it might fairly be described as a "George Dickson year."

Among other Hybrid Teas that have been particularly good on the show-bench, one would name Avoca, Dean Hole, J. L. Mock, Mrs. Cornwallis-West, Lady Alice Stanley, Mabel Drew,

Mrs. A. E. Coxhead and Mrs. J. H. Welch, and we have seen more of John Ruskin, William Sheau, Dr. O'Donel Browne and Yvonne Vacherot than usual.

Hybrid Perpetuals have been very fine in colour; the cool weather has suited them. Messrs. B. R. Cant's second-prize stand in the trophy class at Gloucester stood out in this respect. Gloire de Chedane Guinoisseau, Hugh Dickson, Horace Vernet and Victor Hugo have all been good; but some of the older favourites that used to be in every box were missing this year. Roses like Ulrich Brunner, Mrs. R. G. Sharman Crawford and Captain Hayward were seldom seen, and that old stand-by, Mrs. John Laing, has been conspicuous only by its absence, and very few silver medals have fallen to its lot. Speaking generally, Teas throughout the country have not been good or up to the usual standard. The two Cochet's, Mrs. Edward Mawley and Souv. de Pierre Notting

THE BEST ROSES FOR PEGGING DOWN.

PERHAPS before giving a list of the best Roses for pegging down, I may just say a word or two upon the system and its advantages. Some reader may ask the question: "Why do you peg down Roses, seeing there are such a number of good varieties of compact habit that will grow quite evenly without this artificial aid?" and my reply to this would be that we should be forced to exclude certain kinds that one would much desire to have, only that their exuberant growth bars them from being associated with ordinary bedding Roses. Take, for instance, a bed of William Allen Richardson. It provides us with a glorious rich orange colour, as a rule, but unless pegged down it is very apt to appear

one intended pegging down a bed of Frau Karl Druschki, the plants would be pruned hard in the spring, similar to ordinary Hybrid Perpetuals. The young, vigorous growths as they appear and are long enough are just bent over almost horizontally about a foot from the soil, attaching them to unobtrusive wood or zinc pegs placed at convenient positions. The quantity of bloom from this Rose when pegged down is easily trebled. As regards the Climbing Teas, Hybrid Teas and Noisettes, I would suggest that one or two good ripened young growths of the previous year be retained about three feet to four feet long at pruning-time, and as soon as all danger from May frosts has gone, bend the shoots down as advised above. As the young growths appear from the base of the plants, peg these down also, unless they show flower-buds, in which case allow them to grow erect. William Allen Richardson, Bouquet d'Or, Mme. Pierre Cochet and Céline Forestier will usually send up growths in late summer from their base that are crowned with buds when but 2 feet or 3 feet high. This is when the plants have been previously pegged down in spring. It is advisable to pinch out the ends of the new growths when they have grown about a yard, in order to ripen them and to encourage bloom. Roses of the somewhat erratic growth of Mme. Abel Chatenay and Joseph Hill may be partially pegged down; that is to say, those shoots that start growing so vigorously in a slanting position. Just bend them down almost horizontally. They will not only break into new growth themselves, but basal eyes are encouraged to start out also.

Polyantha Roses of the Orleans and Jessie type often grow too tall for their positions. A simple remedy for this is to peg down the young growths. Each year in late autumn some of the pegged-down growths may be cut away when all flowers are over, or the work can be deferred until spring; but our object should always be to encourage young basal growth, and thus keep the plant in a juvenile condition. For the same reason that we peg down bush Roses, standards may have their growths tied over umbrella fashion, and the result will be far more bloom, although this is sometimes deferred until the second year. The illustration on this page depicts a large bed of that charming variety Lady Water-*l*ow, which is so well suited for pegging down. Good varieties for this purpose, in addition to those already named, are Boule de Neige, Billiard et Barre, Crépuscule, Gustave Regis, Climbing Mrs. W. J. Grant, François Crousse, Conrad F. Meyer, Nova Zembla, J. B. Clark, Juliet, Beauté de Lyon, Ulrich Brunner, Tom Wood, General Jacqueminot, Paul Neyron, Charles Lefebvre, George Dickson, Johanna Sebus, King George V., Mrs. Cornwallis-West, Mme. Wagram, Lyon Rose, Zephyrine Drouhin, Amée Vibert à fleurs jaune, Bardou Job, Avoca, Fairy, Lina Schmidt-Michel, Mme. H. Leulliot, Belle Lyonnaise, Papillon and Rosette de la Legion d'Honneur. DANECROFT.

PART OF A BED OF ROSE LADY WATERLOW, THE SHOOTS OF WHICH HAVE BEEN PEGGED DOWN.

have almost failed us. I should say Mrs. Foley Hobbs is entitled to be called the best Tea of the year. Mme. Constant Souper has been more frequently exhibited than usual. W. R. Smith, A. Hill Gray, Molly Sharman Crawford and Mrs. Herbert Taylor have all been good. Mrs. Myles Kennedy has been often conspicuous; but it has not been a good Tea year.

Southampton. HERBERT E. MOLYNEUX.
(To be continued.)

NEW ROSE MRS. JAMES LYNAS (H.T.).

ON page 516 appears an illustration of this new Rose, shown by Messrs. Hugh Dickson, Limited, Belfast, at the National Rose Society's London Show in July last. It is a beautiful Hybrid Tea, of erect habit, the colour of the blooms being rich bluish pink overlying silvery white. It is one of the best of the gold medal Roses of the season.

ungainly. Another splendid and almost indispensable variety is Frau Karl Druschki. Here, again, its vigour is too often quite embarrassing, and unless annually lifted it must be pegged down. Alister Stella Gray is seen to great advantage when pegged down, and there are several strong yellow Roses, usually classed as climbers, that are very effective when pegged down, producing shades of colour much needed among bedding varieties.

Good crimson Roses, too, are still scarce for massing, and if we can employ such as Hugh Dickson, Sarah Bernhardt, Gruss an Teplitz and Florence Haswell Veitch for this purpose, they would be warmly welcomed; but to use such Roses as bedders without pegging them down would make them quite out of harmony with other bedders.

Generally speaking, it is the strong young growths that are the best for pegging down. Supposing

GARDENING FOR BEGINNERS.

PERGOLAS, TRELLISES AND ARCHES FOR ROSES.

C LIMBING. Roses, however strong-growing some of the varieties may be, require substantial supports on which to train the branches if they are to prove satisfactory. Although substantial supports are needed, it does not follow that they must be clumsy in appearance. Strength may be secured by using really light timbers if the latter are properly prepared and erected in a manner to form a neat-looking structure.

Suitable versus Unsuitable Wood.—Rustic trellises and other kinds of structures are erected in gardens in vast numbers now, and for a time—usually about three years—these erections look very well; then they simply tumble down when a strong gale blows. Green wood, chiefly Birch and Beech, is used. The Birch rots, inwardly first, and then crumbles away; the Beech becomes useless through fungus growing on it and through decay. Such timber, even when of great initial strength, is useless for our purpose. Indeed, it is very annoying to find the structure falling down just when the branches of the plants have covered it, as it is such a difficult matter to erect another under the branches. Oak, Ash and Hazel are the best kinds to use for arches, pergolas, &c. These timbers last a long time, especially when nicely seasoned and prepared. Then squared posts with caps on and planed laths of just medium strength find much favour in these days for formal trellises and pergolas. Here, again, strength may be secured if the posts are well prepared and the whole of the wood well saturated with creosote.

How the Timber Should be Prepared.

It is bad policy to use green wood full of sap, or to creosote timber saturated with water. Give the laths and planed posts two coats of creosote. The liquid will go right through the laths, and the portion above the ground, being exposed to the drying winds as well as rains, lasts in good condition for many years, because it dries up soon after rain has fallen. It is far more important to prepare the part of each post that is buried in the soil. Some are content to creosote that portion, others to char it. The charring is the most effectual, as simply creosoting will not do. The best plan is to first char and then apply three coats of creosote. The charring dries up all internal moisture as well as rendering the outside part proof against decay. Much mischief results when there is internal moisture, as no matter how well the outer crust is preserved, the inner portion will continue to decay. While in a dry state the creosote penetrates right through an ordinary-sized post. Both the charring and creosoting should be done several weeks prior to the fixing of the posts in the soil. Also, char each post several inches above the ground-level, as very often posts rot off there while the portion below remains sound. Some good ready-made rustic arches or trellis fences can now be

purchased from advertisers in THE GARDEN, but readers will do well to avoid cheap, flimsy structures that are offered by dealers of bad reputation.

Good Positions for Pergolas, Trellises and Arches.—The pergola should be straight and run at right angles from some central point of building. Branching portions of the pergola should also be at right angles. Trellises must be erected to form an ornamental screen or shelter to some quarter of the garden—a screen for the protection of other kinds of plants than Roses, or for beds of dwarf or standard Roses, or to secure privacy for the

excellent designs in ironwork are now offered by one or two firms which make a specialty of this kind of work.

Mistakes to Avoid.—The greatest mistake to avoid, after duly preparing the posts and other necessary timber, is that of fixing the posts too close together and too low. The width of the pergola or arch should be at least 6 feet 6 inches; but if there is ample space, make it 7 feet 6 inches or even 8 feet, and quite 7 feet high, because the branches of the Roses, when the latter are established, will require much space to grow in, and persons should be able to pass through the pergola or arch without the slightest inconvenience. Moreover, they ought to be able to enjoy to the full the manifold beauties of each variety of Rose grown.

A RUSTIC ROSE-ARCH OF GOOD PROPORTIONS. THE POSTS ARE 4 FEET 6 INCHES APART EACH WAY, AND THE HEIGHT OVER ALL 5 FEET.

owner. Arches ought to be built in positions to denote a path leading to some other part of the garden, to break up a line of trellis, to span paths where they meet, or to form a series of arches over a long path where it would not be advisable to erect a more close-fitting structure such as a pergola. They must always be of broad dimensions and lofty. Umbrella-shaped erections look really charming in a Rose garden or as isolated features on a lawn. There are many quick-growing varieties of Roses that will soon cover such a structure, and then a feature is secured quite distinct from others in the same garden. Although iron trellises and pergolas are often condemned, they are very useful in Southern Counties where very severe frost is not experienced. At Kew the Roses flourish on iron posts and chains, which have the advantage of being almost imperishable. Some

HOW TO RETAIN SOIL MOISTURE.

Soil moisture is the most important feature of all in gardening, because the power of imparting moisture to the plant is indispensable. Yet the elementary laws which govern it seem to be much misunderstood by amateurs, or, at any rate, often neglected. Much more is now known about the physics of the soil than was formerly the case, and the fineness or coarseness of the soil particles and their composition is found to be intimately connected with this most important subject. This part of the business is where so many people fail. Surface mulching is now well understood as a means of keeping in moisture; but the ground work is even more important, because on it depends whether a soil will store and hold water or not, and there is an enormous difference between soils in this respect.

It may surprise some growers to learn that the wettest soil does not always supply the most moisture to a crop. It is not merely the water content of the soil which has to be considered, but its power of giving this up to plants which is so important. We know that the saturation power of the soil depends partly upon the spaces left between the soil particles, but more especially in their size, and that in an ordinary soil these amount to as much as about forty per cent. of the whole. But this can be much increased if chalk or vegetable matter or good loam forms a certain portion of the soil.

What the cultivator wants is a soil that will give up its water as well as retain a good quantity, a happy medium between clay or peat and sand, and thus he should strive to make it if it does not exist naturally. Manure or vegetable matter is the most serviceable stuff to use, generally speaking, and some powdered chalk is useful if deficient in the soil. A fine soil should be aimed at, and drainage is all-important, because, after all, soils are most fertile when they are only about half saturated, or rather more, and air and heat can then get in.

GIRVAISE TURNBULL, F.L.S.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Flower Garden.

Planting Beds.—When beds are to be planted with bulbs as well as with a covering plant, such as *Myosotis*, *Arabis* and *Violas*, it is wise to plant the bulbs first.

Covering Plants, such as mentioned above, should not be planted too thickly, or the bulbs as they come through may be spindly in growth. Many subjects may be used, such as *Primroses*, *Polyanthuses*, *Wallflowers*, *Aubrietias*, *Arabis flora plena* and the variegated form *Viola seedlings*. I find, are more hardy, and make the best show early in the season; but, whatever is used, due consideration must be given so that the plants when in flower either harmonise or pleasantly contrast with the bulbs.

Double Planting is sometimes practised to secure a longer season of flower, and where the varieties are carefully selected, the results are indeed pleasing. Thus early-flowering, Darwin, or May-flowering *Tulips* may be planted alternately, and in the same way *Hyacinths* and a late variety of *Narcissus*. I have also seen *Crocuses*, *Hyacinths* and late-flowering *Tulips* form a succession which proved very effective. *Crocus Maximilian* (a delicate shade of lavender) is one of the most beautiful subjects for the early spring garden.

The Herbaceous Border.—There still remain a few subjects in bloom, but in most cases the plants are now in a fit condition for cutting down; in fact, the border should now be thoroughly gone over, pulling up all the annuals, cutting down all matured foliage and growth of the herbaceous plants, and lifting anything that it is desirable to keep from getting frozen. Some of the more tender subjects are best given a little protection over the crowns, and dry ashes and leaf-soil are both useful for the purpose.

Replanting.—There is a great diversity of opinion as to the best time to transplant the various subjects in the herbaceous border, though we are all agreed that borders do better when lifted every second or third season, and many subjects may be lifted and split up every year with advantage. The nature of the soil, I think, should govern the time when it may be done. On light soils it may be done at any time from October to March, preference being given to the autumn months, as then the plants get well established again and are better able to withstand drought. On heavier and colder soils the early spring, I think, is better, as many subjects if split up and replanted in the autumn will die during the winter, there not being the same tendency to make roots quickly in the cold, heavy soil; while if a fairly dry period in late February or March is selected in which to do the work, the chances are that the plants will make root and grow away fairly quickly. At whatever season the work is done, good, deep trenching should be practised and a liberal dressing of well-rotted manure given to the borders; this will greatly modify the need for watering during the summer months.

Sweet Peas should be sown at once for the ordinary summer flowering out of doors. Pots or boxes may be used at the discretion of the grower, placing them in a cold frame after sowing. This should be kept well ventilated as soon as the seedlings are through the soil.

Plants Under Glass.

Stove Plants generally will not now require so much moisture either at the root or overhead. *Dracenas* especially not caring for this latter during the winter months; but as the necessity arises for more fire-heat, the need for damping the stages, beds and floors will also increase, this to maintain the necessary atmospheric moisture to keep down insect pests.

Acalyphas that may have become unsightly through using them in the conservatory or the house should be cut down, retaining sufficient of the cut-down plants to furnish a supply of cuttings for the spring.

Cinerarias.—These are making rapid growth, and should be spaced out in the houses or pits as they require it. If it is desired to make really large specimen plants, a few of the strongest may be potted on again; but 9-inch pots are large enough for any purpose.

The Kitchen Garden.

Preparing the Ground.—After this date there will be no further planting to do, and as the various plots of ground are cleared they may be prepared for digging or trenching, the latter for preference. The rubbish-yard, where there has been a fire off and on all the season, will no doubt yield a good supply of wood-ashes and burnt earth, and if this is wheeled on while the weather is dry, trenching may be commenced as soon as the men are freed from other work.

Old Hot-Bed Manure may also be wheeled on to the ground, or may be stored under an old shed, where it may be turned and mixed with soil during bad weather, when it will be ready for the making up of frames for early crops or for the hundred-and-one purposes for which it good, rich compost is so necessary.

Fruits Under Glass.

Peach-Houses and Vinerias.—In many establishments these will be filled with such plants as *Chrysanthemums*, and, providing proper care is taken, much harm may not result; but at all times a close, moist atmosphere must be avoided, also undue heating of the hot-water pipes must be guarded against. A small amount of heat in the pipes will be beneficial rather than detrimental, providing a full measure of air is admitted at the sides as well as at the tops of the houses. A temperature high enough to raise the sap in the Vines or Peach trees before the proper time is what must be guarded against, or the growth in the early stages next season will not be all that is desired.

Tomatoes that are setting their fruit must be carefully gone over each day with a camel-hair brush or rabbit's tail. At this season over-watering must be strictly avoided, or sappy growth will result. The temperature of the house also must be kept fairly even; 55° to 60° at night, with a crack of air on, should be about right, allowing a moderate rise during the day when the sun is shining, giving as much air as is consistent with the existing weather conditions.

THOMAS STEVENSON.

(Head-gardener to E. Mocatta, Esq.)

Woburn Place Gardens, Addlestone, Surrey.

FOR NORTHERN GARDENS.

The Flower Garden.

Lifting Gladioli.—*Gladioli* flowered earlier than usual this season and are now past. Cut away all flower-stems, lift the plants carefully, and store them in boxes in a shed, covering the bulbs with sand or some light soil till the stems die down by a natural process.

Lifting Montbretias.—Equally successful cultivators differ in their methods with these fine autumn flowers. Some lift them and run them out close in nursery lines in a sheltered spot, working in a little light soil among the bulbs as the work proceeds; while others box them up in propagating-boxes among flaky soil and winter them in a shed or a cold frame. The following is my method: I pot them up into 6-inch pots in light, flaky soil, about five bulbs to a pot, and winter them in a cold frame; they are hardened off in early spring after growth commences, and are planted about the middle of April. This means a little extra trouble, but the results amply justify the means.

Lifting Tender Subjects.—In addition to those indicated, all tender or half-hardy subjects should either be lifted or protected where they are. Such things as *Heliotropes* and *Salvias*, if sufficient stock has not been propagated successfully, should have a portion of the plants cut over and potted up to furnish cuttings for spring propagation.

The Rose Garden.

Hoeing.—Run the Dutch hoe through the beds and borders to rid them of any weeds and to keep the soil aerated. Beds or borders which have had a groundwork of *Violas* should now have these removed, and the soil be rather deeply stirred with the hoe.

Late Blooms.—Free-flowering varieties, such as *Caroline Testout*, often furnish a good deal of bloom right up to November. Any decaying blooms coming in contact with those unopened should be promptly removed, or the latter will be damaged.

Gross an Teplitz.—This is the time when this fine autumn Rose shows its superiority.

The Shrubbery.

Planting Evergreens.—This work should be done as soon as possible, so that the plants may get a hold before winter. If drying winds should occur, newly-planted subjects will be benefited by being sprayed over during the early afternoon. The less hardy subjects should receive a mulching; this will help to maintain more equable conditions at the root, both as regards moisture and temperature, and it is a necessity where keen frosts occurs.

Propagating Evergreens.—This is a good time to propagate evergreen shrubs, and a suitable place in which to put the cuttings is a cold frame behind a wall, in which a layer of sandy soil has been placed and made firm. Finish with a thin layer of sand.

Plants Under Glass.

Chrysanthemums.—If green fly appears, vaporise at once. Stop feeding when the blooms are half opened. Where exhibiting is contemplated, any too precocious blooms should be shaded with tissue-paper during bright sunshine.

Cinerarias.—Those intended for a spring display will now be ready for the final shift. The size of pot will have been determined at previous pottings. *Cinerarias* prefer a rather light, rich soil. A cool house, near the glass, will be the best position for them now. If the leaf-miner appears, spray with *Quassia Chips Extract*, which makes the leaf distasteful to the miner.

Sponging.—This is an important operation among foliage plants, as it not only improves their appearance, but rids the foliage of dust and dirt, thereby enabling it the better to perform its functions as the respiratory organs of the plant. Plants having this attention now will look fresh and bright during the dull days of winter.

Fruits Under Glass.

Late Peaches.—Trees that have not yet ripened their wood should have the benefit of a little fire-heat with a good deal of ventilation day and night, the object being not to excite growth, but simply to ripen the wood. Maintain dry atmospheric conditions.

Pruning Vines.—Whenever the Vines become defoliated, they should be pruned without delay. As already advised, a sharp knife is preferable to the secateurs for this work. One or two eyes are sufficient to leave, therefore avoid leaving long snags.

Painting.—Any of the early houses requiring the woodwork painted should have that attention as soon as pruning has been finished. Later on it is more difficult to get the woodwork quite dry, a condition essential to the work being efficiently done.

The Hardy Fruit Garden.

Propagating Gooseberries.—These and Currants may now be propagated. Select fairly vigorous but well-ripened shoots, and take them off with a heel, cut away a few inches of the immature wood at the point, rub out a few of the lower buds, and trim the base of the cutting with a sharp knife. The cuttings should then be inserted in sandy soil, made firm, on the open border, and receive a good watering to ensure the exclusion of air, a condition which will accelerate the process of rooting.

Planting Loganberries.—Where a planting of these is to take place, the ground should be manured and trenched, and a trellis erected on which to train the plants. I recommend a double trellis about a foot wide, the fruiting canes being trained up one side and the succession canes up the other, these being transposed annually, of course. Recently, however, I heard of a double trellis, V-shaped, the fruiting canes being trained up each side, the succession canes growing up the centre.

The Vegetable Garden.

Storing Root Crops.—Carrots and Beet should now be stored without much further delay, as described in *THE GARDEN*, September 27, page 489.

Digging and Trenching.—This work should be carried out as opportunity offers. Autumn manuring is preferable to spring manuring, and the character and amount must depend upon the crop for which it is intended. Avoid rank manure where tap-rooted crops are to be grown. Bastard-trenching, by which the top spit is left in position, is preferable to regular trenching.

EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, a payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W. C.

NOTES OF THE WEEK.

Treatment of Hardy Ferns.—Where hardy Ferns are grown, one often finds the fronds cut off as they get brown, the idea being to make them tidy. This is a great mistake as far as the plants are concerned, as they act as a natural protection to the crowns during the winter. In addition, there is a certain amount of beauty in fronds that have lost their bright green tints, as may be seen in our woods in winter and early spring.

Edging for Planting Under Trees.—Few plants are more suitable as an edging under trees than the Ivy, and even in the open it is excellent for an edging for the shrubbery or similar positions. It gives little trouble after it is planted, apart from being cut once or twice during spring and early summer. It should be planted now, and if it has long trails, so much the better. These should be pegged down to keep them in their place.

Dwarf Scillas for Planting in the Grass.—The value of planting bulbs in the grass is being realised more and more every year, and among the early-flowering ones few are more charming than the dwarf Squills, *Scilla bifolia* and *S. sibirica*. Either by themselves or planted among Snowdrops, they give a very pleasing effect. They are not particular as to position, whether in full sun or partial shade; but if planted in the last named, they will be found to last much longer in flower. Bulbs can be purchased quite cheaply, and should be planted now without delay.

The Thornless Rose.—A few autumn blooms of the Thornless Rose, *Zephyrine Drouhin*, remind us that this charming variety is not grown nearly so much as it ought to be. Considering that it was raised so long ago as 1873, it is difficult to understand why it is not found in more gardens. The flowers are bright, glowing carmine pink in colour and deliciously fragrant, inheriting this latter desirable feature from the Bourbon Roses, of which it is a hybrid. It is very vigorous, and consequently makes an excellent pillar Rose, or it may be used as a low garden hedge, where light pruning only will be required. The stems are thornless; hence its popular name.

A Remarkable Graft Hybrid.—Commenting upon the peculiarities of the graft hybrid *Cratægomespilus Dardari*, the current issue of the *Kew Bulletin* says: "This graft hybrid shows a phenomenon, unique so far as we are aware, of one kind of tree (not as yet, however, one individual) producing four types of growth, two of which are distinct species and two of a hybrid or intermediate nature, viz.: (1) *Cratægus monogyna* and (2) *Mespilus germanica*, the parent species; (3) *Cratægomespilus D'Asnieresii*, hybrid approaching No. 1; (4) *Cratægomespilus Dardari*, hybrid approaching No. 2. *Laburnum Adami* has not been known to produce more than one hybrid type of flower besides those of its two parent species (*Laburnum vulgare* and *Cytisus purpureus*), three in all."

National Sweet Pea Society.—The annual general meeting of the National Sweet Pea Society will be held at the Hotel Windsor, Victoria Street, Westminster, London, S.W., on Monday next, October 20th, commencing at 2.30 p.m. A conference will be held at the Hotel Windsor at 7 p.m. on the same day, when Mr. J. S. Brunton will give a lecture, entitled "The Sweet Pea Industry."

Mint for Winter Use. This useful garden herb is often in demand during the winter, and although a good supply of dried Mint may be at hand, green leaves are always preferred. As forcing is a very easy matter, there is no reason why fresh Mint should not be obtained. Insert a quantity of roots in a box at the present time and put them in a warm place, keeping them watered. A succession may be kept up by the introduction at intervals of an additional supply of roots.

A Beautiful Water Lily.—Several plants of the beautiful Australian Water Lily, *Nymphaea gigantea*, have been very attractive in the Victoria Regia House at Kew for several months, and are still (mid-October) bearing numerous fine flowers. The plant may be described as a glorified *N. stellata*, both leaves and flowers being finer than in that species. The flowers, which range from 6 inches to 8 inches across, are produced on stout stalks 12 inches or 18 inches above the water, and are made up of numerous shapely, bright blue petals, which enclose a central mass of rich golden stamens.

A Beautiful Late-Flowering Torch Lily.—Most of the Torch Lilies are at their best from July to September, but there is one, *Kniphofia aloides maxima*, which makes a delightful show in October. Varieties such as this, which help to prolong the flowering season and brighten up the borders in late autumn with the Michaelmas Daisy, are worth encouraging. Growing 5 feet to 6 feet in height, the stout stems are carrying quantities of small, tubular flowers. These, when open, have a yellow effect; but by far the most telling colour is the coral red of the flower-buds, of which in early October there are a great number crowning the spikes.

Apple Blenheim Orange Fruiting on Young Trees.—This excellent Apple is often passed over at planting-time, as it is reputed to be very slow in coming into bearing. Instances have been cited where trees have not borne fruit until attaining the age of twenty years. While this may be true of standard trees grown upon Crab stock, it cannot apply to bush trees grown upon Paradise stock and annually transplanted. Some exceptionally fine examples of the latter were shown at the last meeting of the Royal Horticultural Society by Messrs. James Veitch and Sons. The trees in question, lifted from the open, were less than 4 feet in height, and carried an average of twelve handsome fruits per tree, while the age of the trees was only four years!

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Rose Augustine Guinoisseau.—I had the same experience last year that Mr. Cobbold has had this (see page 482). One of the Augustine Guinoisseau bushes threw a growth bearing two typical La France Roses. I have been looking out for the same irregularity this year, but it has not occurred. The wood was weak and was pruned away this spring, and I regret now I did not bud some stocks from it to see what would come.—W. J. PANCKRIDGE, *Petersfield*.

Androsace lanuginosa for the Rock Garden.—This is one among the many beautiful varieties of *Androsace* that should be largely grown for the rock garden, especially where the more tender or difficult species fail to grow. It has been in bloom

the position I describe, I have never known them to fail to flower abundantly. Covering a large portion of a wall 60 feet high on a dwelling-house outside of Cromer in Norfolk is a plant of this Rose with a stem 5 inches in diameter, which must have been planted quite early; the variety was introduced by Damper in 1823. Even this plant never fails to give a crop of flowers.—E. M.

The War on Wasps.—I was very interested in the war on wasps mentioned in your issue of October 4. I thought you might be interested to know what I have done in destroying these pests. In 1910 our kitchen garden wall was repaired and 300 queen wasps were killed in the month of November. In 1911 I destroyed 245 nests, in 1912 50 nests, and this season I have taken 267 nests. I have never seen so many wasps as we have had here this year. I have killed 51 queen wasps and one hornet this last

where in the only books I have on fungi, namely, Cooke's "British Fungi" and Badham's "Esulent Fungi of England."—G. JEVILL.

Abnormal Growth in Plants.—I thought it might interest the readers of THE GARDEN were I to draw attention to two cases of what I consider abnormal growth in the gardens here. The first is that of two Hollyhocks among a batch of seedlings. The rest of the batch, although fairly tall, are nothing out of the ordinary, but the respective heights of the two in question are 12 feet and 11 feet 11 inches. They both have double flowers of the same shade, a deep rose pink. The second case is that of a plant of *Cobaea scandens* which was planted in an unheated verandah last April. Since that date till early October one of the leading shoots has made 39 feet of growth, and three other shoots have made over thirty-six feet of growth. *Cobaea scandens* is well known as a rampant grower, but for a plant out of a 5-inch pot the growth seems to me to be phenomenal.—CHARLES COMFORT, *Broomfield Gardens, Davidson's Mains, Midlothian*.

An Interesting New Zealand Garden.—Seeing the results of the Rock Garden Competition in THE GARDEN for June 14, I think you may care to reproduce some of the photographs which I am sending you. These were taken by my father (Mr. Kinsey) quite recently. As the *New Zealand Graphic* asked permission to reproduce some, I think the letterpress they give describes the gardens. My father and I have always been keen amateur gardeners. During the last thirteen years my own garden in Dunedin has become full of interest. A clump of *Ranunculus Lyallii* has bloomed and flourished well since I planted it several years ago.—MAY MOORE. [The letterpress kindly sent us by our correspondent describes in detail the gardens of Mr. Kinsey, a view in which is reproduced herewith. The outlook is superb, stretching from the cliffs near the entrance to Lyttleton Harbour, to the distant Kaikouras and Mount Hutt. The name of this week-end residence of Mr. Kinsey is Te Hau O Te Atua. Here the late Captain Scott stayed with Lady Scott before proceeding on his last and fateful journey to the South Pole.—ED.]

Aster Beauty of Colwall.—It might be said with but little fear of contra-

dition that not only is this the finest Michaelmas Daisy extant, but the greatest addition to autumn-flowering herbaceous plants that has yet seen the light of day. It is also an acquisition. Indeed, no plant of my acquaintance is possessed of the illuminating power of this Aster when seen in well-cultivated groups. Good cultivation, however, is required, and will be repaid a thousandfold when the handsome pyramids of rich violet blue flowers stand out in unrivalled splendour in late September days. This year, by reason of the exceptional spell of sunshine that has been experienced, the great groups of it have assumed an unusual brilliance, and those who plant for effect—those who can garden with hundreds of such plants—can surely have no finer subject than this. It should, however, be cultivated and given room for development if all the sumptuous beauty of which it is capable is to be realised in its fullest measure.—E. H. JENKINS.

A VIEW IN A READER'S GARDEN AT DUNEDIN, NEW ZEALAND. IT WAS HERE THAT THE LATE CAPTAIN SCOTT STAYED BEFORE STARTING ON HIS LAST VOYAGE TO THE SOUTH POLE.

since May and is still flowering, and will continue to do so till the cold weather sets in, when it requires a little shelter in the winter. Before planting this the ground (stiff clay) was taken out 18 inches deep and filled in with suitable compost, as given by Mr. Clarence Elliott for the moraine garden. Not only this species, but several others have been quite a success, especially through the past dry summer, when otherwise they would have been all scorched up.—A. B. WADDS, *Englefield Gardens, Keading*.

Yellow Banksian Rose.—If "C. T.," page 482, will remove his plant of Yellow Banksian Rose to a south wall and give it generous treatment, he will be rewarded annually with a full crop of its beautiful yellow blooms. A fence does not provide the necessary warmth needed to prepare the current season's growth, with the flower crop to follow the next year. Where plants are growing in

month that were seeking their home for the winter in our stovehole. I have destroyed the nests with cyanide of potassium in the dry powder, and if trodden in the next morning I have found it most satisfactory.—W. W. RICHARDSON, *Marks Hall Gardens, Coggeshall, Essex*.

Fungus Name Wanted.—Will any mycologist kindly tell me the name and anything that is known of the properties of a large fungus that appears nearly every year at this season in and near the north side of a hedgebank of peaty, sandy soil under Scotch Firs? In appearance it is exactly like a large bath sponge, only slightly lighter and livelier in colour. One mass is nearly a foot wide and 6 inches to 7 inches deep; another is smaller, but perhaps not full grown. The texture is tender and easily breaks up. The appearance suggests some affinity to *Morel*, but I can find no mention of it either under *Morel* or else-

Virgilia lutea.—This tabaceous dwarf tree is at present at its best, the foliage having assumed its autumnal chrome yellow colouring. It has never flowered here, but the effect it produces in autumn compensates for all other failings.—R. P. B., *Lynninghame, Prestonskirk, N.B.*

The Hardiness of Nicotiana affinis.—The fragrant and beautiful *Nicotiana affinis* is hardy in some gardens I have visited, but it was quite an unexpected thing for me to see a few old plants in Tollerross Park, Glasgow, the other day. They were growing at the end of one of the greenhouses in the enclosed ground at the back, and had been there for several years unsheltered. Mr. Wilson, who has charge of Tollerross Park, under Mr. James Whitton, informed me that the plants had proved quite hardy. *N. affinis* is not usually hardy in gardens so far North as Glasgow and in a climate such as is to be met with there.—S. ARNOTT.

Pruning Rose Dorothy Perkins.—The orthodox method of pruning this and other climbing Roses is to remove the whole of the last season's wood that gave flower this year, to make space for the current year's growth, which is intended to give the next year's flower crop. While not saying one word against this method, I do not think it is necessary to cut away the whole of last year's shoots; if the strongest of these are allowed to remain, they will give quantities of flower next year and will aid in making a much thicker screen where such is necessary. I have a hedge of this Rose, 10 feet high, which has scarcely been pruned at all during the last six years, and how it blossoms yearly in such profusion surprises many people.—S. H.

The Nerines.—I was greatly interested in the article on these lovely bulbous plants which appeared in the issue for September 13, because it recalled to my memory a very fine batch that used to be in Blenheim Gardens, Woodstock. They may still be grown there; but my reference is to ten years ago, at which time they were in splendid condition, flowering most freely. To the best of my recollection they were in 7-inch to 9-inch pots, and full of bulbs, even to overcrowding, which state evidently betokened their having been undisturbed for many years. As they passed out of flower they used to be stood on shelves in a dry house, where the sun could play upon them continuously until they began to throw up spikes again. The variety was known as Fothergill's major. Incidentally, the Nerine does not seem to be largely grown, for it is seldom one can see it when looking round a garden, big or small.—C. TURNER, *Highgate.*

The Failure of Pears.—In the present extreme shortage of Pears it may be worth while to preserve a record of the doings of various sorts, in order to establish, if possible, some general principle. My garden, I should mention, is well protected by downs on the north and east, and largely by the church on the west. It is somewhat exposed to south-west winds straight off the sea. I have hardly any wall. My record is: Beurré Lebrun and Prince Imperial, fair crop, less than usual; Doyenné du Comice, two on wall, twelve each (one of these, a noble tree figured in THE GARDEN some years ago, has had 188); three in open garden, none; Marguerite Marillat, ten; Maguete, four; Alexandrine Douillard, two; Le Lectier and Durondeau (both on wall), one each; about twenty-five others, all of the best sorts, none. My impression is that in the long spell of bad weather this spring, those which were early enough to have set the

bloom before it, and those which were not then out at all, partially escaped, but I cannot altogether fit my list to this theory. Perhaps some other growers will give you their experience. G. E. JEANS, *Shorewell Cottage, Isle of Wight.*

A Noble Border Plant.—*Physalocia decandra*, perhaps better known as the Red Ink Plant, though easily cultivated and quite hardy, is rarely met with in our Irish gardens. When planted in a favourable position, it attains a height of from 8 feet to 20 feet. A plant established in the herbaceous borders here annually makes a fine display in the autumn, when the long, summer flower-spikes are loaded with dark purple berries. When established, *P. decandra* needs very little attention unless planted in an exposed position, when a stake will help it to withstand the autumn winds. Propagation is best effected by seed, as the large, fleshy, poisonous roots do not take kindly to dividing. Usually a few seedlings may be picked up in spring from the borders in the vicinity of the parent plant, and if carefully transplanted they will make nice plants the first season. If better known, this plant would undoubtedly find a corner in every garden.—T. LUGGITT, *Woodlawn, County Galway.*

Verbena venosa? What is its Colour?—A large bed planted with pillar-trained, rose-coloured, Stock-flowered Larkspurs, with the interspaces filled with *Verbena venosa* and a broad edging of dwarf *Ageratum*, has attracted some attention this season, and in one instance the colour of the *Verbena* gave rise to not a little discussion, violet, purple and heliotrope being by different persons assumed to be the correct colour description. The colour is, of course, one by itself, and on turning up a few books I had it noted as rosy violet, and purple. I myself have always looked upon it as giving on the whole a violet effect, and for certain purposes, an indispensable colour in the flower garden. I wonder what some of your readers who are acquainted with colours would describe it—not so much the colour of an individual flower-head as the effect in a grouped mass. This species is not nearly so much grown as it deserves to be, and is not often seen in gardens at the present time, though forty years ago it was used in the bedding designs of that period, with much effect. It is a South American plant, not everywhere hardy, but in the milder districts it is distinctly hardy herbaceous, though the best results are obtained by annual propagation. This may be done in three ways. One is to sow seeds in heat very early in the year, taking the precaution to steep the seeds in water for a couple of days before sowing and never allowing them to feel the effects of dryness. At the best the seeds germinate rather erratically. The underground stems provide another method of increase. These are cut into short pieces, and, being covered with light soil, produce growths from each eye, and after roots are formed they are transplanted into ordinary cutting-boxes or pots. Another way is to strike the shoots which are forced into growth from the stems, and by this means a larger increase is possible. To those who are unacquainted with the plant it may be explained that it grows from 6 inches to 2 feet in height, the latter in soil well cultivated.—R. P. BROTHSTON.

FORTHCOMING EVENTS.

October 21.—Royal Horticultural Society's Exhibition.

October 22.—Hereford Fruit and Chrysanthemum Show (two days).

THE GREENHOUSE.

SEASONABLE NOTES ON CHRYSANTHEMUMS.

DURING the early part of October all the plants now grown for the production of exhibition blooms will be placed under glass. As amateur cultivators generally have more garden space for the plants during the summer-time than greenhouse room for them in the autumn, a close selection should be made so as to make sure that the best plants with the most promising buds have the most favourable positions. Overcrowding, to a considerable extent, may thus be avoided. It is not a difficult matter to decide which plants will prove the best satisfactory, and, of course, their entire exclusion would make a great difference to those bearing fine buds. Although the lower leaves have really done their part in the building up of the plants, it is better to try to retain them as long as possible now by attending the plants ample light and air.

Dressing the Blooms.—Twenty years ago the dressing of the blooms was a very important matter, when incurved varieties were largely grown. Many varieties of the incurved section have Japanese blood in them, and some dressing is necessary to avoid coarseness. The dressing that I recommend now takes the form of the simple removal of short, twisted or otherwise malformed petals, which, if left in, would interfere with the proper development of the good, sound petals. The timely removal of bad petals is more effective than leaving all such to be taken out at one time—when the bloom is really fully developed.

Night Work.—If all faded leaves are picked off the plants when the latter are put under glass, the natural harbour for earwigs, and many of these pests, too, will be got rid of; but there will, no doubt, be plenty more to destroy. It is not difficult to catch them on undeveloped buds about eight o'clock in the evening by the aid of a good light suddenly thrown on them, but much more so when the blooms are half open, and later still. Caterpillars that are usually found on the leaves of Zonal Pelargoniums at this season also do much damage to Chrysanthemum blooms, eating away half a bud in one night. If any excrescence be found on the leaves, look carefully under them in the daylight, and, failing to find the caterpillar, examine the opening buds at night. Mildew may also spread on the leaves. Early in the morning, while the leaves are rather moist, throw some flowers of sulphur on them and underneath. The powder will adhere and soon check the spread of mildew. I much prefer to use dry sulphur in this way than a solution of any kind after the plants are housed. It is advisable to group the plants, forming three groups, after they are housed, namely, the earliest or most forward, the medium early, and the latest. I refer, of course, to the state of the opening flowers, and not to the late, medium, and early varieties. So placed, it will be found very easy to attend to the daily requirements of the plants. Lightly shade the more forward blooms, especially those of the chestnut and bronze varieties. Yellow and white-flowered varieties must be kept away from the top ventilators if there is a direct draught on them, as the purity of the petals will be marred by damp spots. Thin screen or tiffany suspended between the blooms and the ventilators will keep away much moisture. Gradually lessen the feeding of all plants bearing half-open blooms, and give clear water only when three parts developed. AVON.

THE CAMPANULAS OR BELLFLOWERS.

(Continued from page 497.)

C. petraea.—A plant which seems more prized for its colour than for anything else, but in reality it is a poor subject. It is upwards of a foot high, with large heads of dull yellow in July, and is a doubtful perennial; in fact, a biennial with almost everyone. Sun and a dry place. Seeds.

C. portenschlagiana.—A valuable plant for sun or shade, rockery, wall, or large moraine. It forms a trailing mass of pretty leaves and handsome, purplish blue flowers in June, July, and even later. The best form is *C. p. bavarica*, or in our. Excellent for any place in the garden.

C. pseudo-Raineri.—This is now very scarce, and was for long sold as one of the forms of *C. G. F. Wilson*, but is a much finer plant than either that hybrid or *C. Raineri* itself. It has large,

and very handsome with its large, drooping cups of exquisite blue in June and July. Division.

C. pumila and **C. pusilla.**—For garden purposes these are practically the same as *C. caspitosa*.

C. raddeana.—A handsome, graceful, easily-grown comparative novelty. In gritty soil in sun it is about a foot high, and has fine deep green foliage and dark blue flowers borne in plenty in July. The flat parts of the rockery or front of the border. Sun or shade. Seeds or division, increasing rapidly at the roots.

C. Raineri.—A delightful plant, beloved of slugs and difficult to keep. It loves the moraine or a sunny chunk, where it gives its large, blue, erect, open flowers on 2-inch or 3-inch stems. Division or seeds. June.

C. rhomboidalis.—A lovely little Bellflower of the *rotundifolia* character, with prettily-formed, deep blue flowers about ten inches or twelve inches high. The level rockery or front of the border. Seeds or division. June or July.

CAMPANULA ROTUNDIFOLIA ALPINA, A CHARMING BELLFLOWER FOR THE ROCK GARDEN.

purplish, open bells in June on a low, rather trailing plant. An open place in light soil suits it best.

C. Profusion.—There are two forms of this lovely hybrid Campanula, which comes very near *C. haylodgensis*. One has more yellow leaves and one lighter blue flowers than the other. Excellent for a dry rockery, wall, or moraine. Division or cuttings. June and July.

C. punctata.—A handsome plant, with long, drooping, whitish bells, spotted like those of a Foxglove, in June. Not very long-lived, but easily raised from seeds, and looking best on a rockery. It is 9 inches or a foot high. Partial shade.

C. pulla.—A lovely gem, which often dies out in gardens, either from winter wet or from slugs. It hates lime, and loves a peaty, rather moist place. Charming drooping bells of deepest blue on 6-inch or 8-inch stems in June and July. Seeds or division. The moraine suits it well.

C. pulloides.—A lovely hybrid, found by some easier to grow than *C. pulla*, which is one of its parents. Good for the same positions as *C. pulla*,

C. rotundifolia.—Under this, our native Harebell, we may group a number of forms. *C. hayloha* and *C. alaskana*, though said by some to be distinct, may well be included. *C. Hostii* is one of the best forms. *C. r. alpina*, deep blue, is very fine. There are various shades of blue and of white among the varieties. The single form of *C. r. soldanellaeflora* is not worth growing, but the double one is interesting. Any soil or position will suit these. Seeds or division. *C. limifolia vaddensis* is very good. All the forms will grow almost anywhere, and flower from June.

C. rupestris.—A beautiful little plant with large, pale blue flowers and rather silvery-looking leaves. Moraine, or dry, sunny rockwork, and resembling *C. fragilis* in its general aspect. Division or seeds. July.

C. sarmatica.—A good rock and border plant, about a foot high, after the fashion of *C. barbata*, with pleasing light blue flowers in July. Any soil, and excellent in every way. S. ARNOTT.

(To be continued.)

THE ROCK AND WATER GARDEN.

AUTUMN IN THE ROCK GARDEN.

MOST owners of rock gardens are apt to think that after June, or, at latest, July, the charm of that part of their garden is gone. To a certain extent this is true. Those who know Switzerland will realise that the spring and early summer are certainly the times when alpine plants are at their best. But this all makes the problem of how to avoid a bare autumn rockery all the more interesting. Just now quite a respectable number of plants may be had in bloom by those who arrange their plans well. It is considered rather bad management if the flower-borders are quite bare at one period of the season, unless, of course, they are planned for a special month.

Why should not this apply to the rock garden? I will enumerate some of the plants that will flower just now. It is a great help if plants of small growth and quite suitable to such a position are grown, even if they are not alpine, and use is even made of annuals to fill up gaps. Of small carpeting plants, *Frankenia*, with pretty grey foliage and a small pink flower, and *Ionopsidium acule*, an annual with pinkish mauve flowers, are both good. The latter is particularly suitable for an edge. *Linaria alpina* is a graceful, feathery little plant. Of the Heaths, *Erica Searlii* and *E. vagans alba* are both in flower just now, and make a very satisfactory mass of dark green, studded with white. *Vittadenia triloba* is a small and most useful plant, not often seen. It has a Daisy-like, pinkish white flower, and is covered with blossom most of the year. It deserves the very highest recommendation. Both *Corydalis dicentra* and *C. lutea* are out. Though neither is a showy plant, their foliage makes a pretty soft-looking mass, and their flowers are not to be despised. The latter grows well in a wall. Stray flowers may be

found on many plants which have really done their flowering season. *Hypericum reptans* and *H. Coris* will make a welcome patch of yellow. *Potentilla Miss Willmott* flowered early in the summer, and is now a mass of silvery pink blossoms. In a damp spot a red *Mimulus* makes a handsome patch of colour. It is worth noting that though it does best by the side of water, it will also grow in quite a dry situation. *Tunica Saxifraga* and *Androsace coronopifolia* (rather similar in appearance) are both out.

To sum up for the benefit of those who are on the look-out for autumn-flowering plants, the following may give useful ideas: *Gentiana asclepiadea*, *Commelina*, *Mimulus*, *Corydalis dicentra* and *C. lutea*, *Frankenia*, *Iberis gibraltarica*, *Oenothera macrocarpa*, *Thrift*, *Linaria alpina*, *Tunica Saxifraga*, *Androsace coronopifolia*, *Ericas*, *Hypericum reptans* and *H. Coris*, and *Veronica*. For foliage, *Sedums* of sorts. For a few stray flowers, *Geranium lancestrisense*, *Campanula turbinata* and *C. t. pallida*, and *Violas*. M. B. RAUCLIFF COOKE.

ROCK GARDEN PLANTS IN OCTOBER.

THOSE who so often bemoan the fact that our rock gardens are devoid of interest during the autumn should give more attention to the plants which flower at that season. On more than one occasion we have printed lists of suitable kinds, and readers have kindly supplied the names of others that can be relied upon to produce flowers when the days are waning. This year a great many alpine plants have been flowering late, and on the 2nd inst. we received from Mr. Maurice Prichard, West Moors, Dorset, a very fine collection. In writing, Mr. Prichard says: "I have pleasure in posting you a box of cut alpines flowering on October 1 in the open. The variety is so great for this time of the year that I was tempted to send a few samples for your table." As the subject

is one of more than usual interest, we publish herewith the names of all the kinds sent: *Achillea tomentosa*, yellow; *A. Kellereri*, white; *A. Aizoon*, white; *Antirrhinum glutinosum* Copper King and Crimson King; *A. gibraltarium*, rose purple; *Aster Mrs. Berkeley* (white Michaelmas Daisy); *A. hybridum roseum*, pale rose; *A. sericeus*, mauve; *Asteriscus maritima*, yellow; *Bonninghansenia albiflora*, white, with Rue-like foliage; *Calandrinia umbellata*, deep purple; *Campnula pusilla*, deep blue; *C. rotundifolia alba*; *Caleolaria alba*; *Cheiranthus Marshallii*, pale orange; *Chanostoma lespida*, pale bluish; *Coreopsis rosea*, pale rose; *Coronilla albo-roseum*, rose and white; *Convolvulus mauritanicus atrocaryleus*, blue; *Dianthus deltooides Brilliant*, brilliant rose pink; *D. Prichardi Brilliant*, rosy pink; *Erodium hybridum*; *Febena abyssinica*, pale mauve; *Lysimachia Henryi*, yellow; *Heeria elegans*, rose purple; *Hypericum polyphyllum*, *H. egypticum*, *H. olympicum*, *H. orientale* and *H. empetrifolium*, all yellow; *Linaria anticaria*, pale yellow, with bronze lip; *L. alpina*, mauve blue, with orange scarlet lip; *L. multipunctata*, orange yellow; *L. rosea concolor*, pale rose; *L. repens alba*, white; *Mecomonopsis cambrica plena*, yellow; *M. c. aurantiaca plena*, orange scarlet; *Moringia muscosa*, white, very tufted; *Myosotis azo-*

ricus, violet; *Oenothera riparia*, dull orange scarlet; *O. mexicana rosea*, rose; *O. taraxacifolia*, canary yellow; *Nepeta Mussinii*, deep lavender; *Origanum dictamnus*, dull rose; *Pentstemon campanulatus*, dull crimson; *Phyteuma lobelioides grahns*, deep blue, Campanula-like flowers; *Primula Munroi*, white; *P. capitata*, deep blue; *P. bulleyana*, orange; *P. Poissonii*, rose purple; *Polygonum vacciniifolium*, rose pink; *P. capitatum*, rose pink; *Saxifraga cortusifolia*, white; *Scutellaria indica japonica*, lavender blue; *S. hastata*, blue; *Silene laciniata*, scarlet; *Solidago brachyphylla*, yellow; *Stachys cocumea*, dull orange scarlet; *S. corsica*, pale bluish; *Verbena venosa*, purple; *V. Teneri Mahonettii*, purple, edged white; *V. radicans*, deep mauve; *Veronica Bidwellii* (Miss Willmott's hybrid), pale blue; *Viola Oetholica*;

V. Jackanapes, lower petals yellow, upper velvety brown; *V. olympica*, deep sky blue; *Vittadema triloba*, white, Daisy-like flowers; and *Wahlenbergia vnicelliflora*, periwinkle blue.

THE ROSE GARDEN.

IN A HAMPSHIRE GARDEN.

SOME OF THE NEWER ROSES.

CONTINUING the general review, I come now to the most "important" class of all—I mean the garden Roses. What heresy this must sound to some! What would the Rev. Foster Mellor have said to such a statement. And yet it is true. The most important by reason of its numbers, variety and general interest. Why, for every exhibition Rose grown

Rose world! And then I passed on down the garden and stood before a bush of Irish Beauty, with a spray of its bloom just opening, the centre or crown bud tully out; of the others some were thinking about it, while some were still tight buds, hardly showing colour. Naturally, it was the centre flower that attracted my attention, and it was larger than usual. The first flowers are nearly always the biggest and this one was at the stage of its highest possible beauty, and I, with all the magnificence of the other Rose still before me, found myself exclaiming, "No; this is the most beautiful, after all! The simple white flower—only a single!"

I think possibly the best way to deal with the garden Roses will be to divide them into colours, dealing with them as bedding Roses that have been particularly good this year. One starts with pink (all shades): Miss Cynthia Forde, Mme. Second Weber, Mme. Léon Paul, Bertha Gaults and Lady Alice Stanley. I think I must confine myself to five of each colour; three plants of each would make a fine bed for anyone who "must" grow mixed Roses. They are, I am afraid, in the majority, and all these five would, as it happens, mix well. Flesh tints: Mrs. Amy Hammond (a delightful Rose this), Pharisæer, Grace Molyneux, La Tosca and Lady Ursula, all good, strong growers that would be called tall in comparison with the set of five pinks. Cream and pale yellow: Mme. Melanie Souper, Lady Greenall, Melody, Verna Mackay and Mrs. Harold Brocklebank. Melody is probably the least vigorous of these five, but cannot be left out, although the question of habit of growth is of much more importance in the case of mixed beds. Reds: A real good bedding red is still to seek. (I consider, despite its growth, Hugh Dickson is still the most satisfactory, but that is hardly new.) Mrs. Muir McKean, Lieutenant Chaure, Mrs. E. Powell, Leslie Holland and Richmond are all good growers. Yellows: Lady Hillingdon (the best yellow garden Rose), Miss Alice de Rothschild, Duchess of Wellington, Harry Kirk and Mrs. A. Petrie. White I shall not be able to find five in this colour: Mrs. Herbert Stevens, Molly Sharman Crawford,

CAMPANULA PORTENSCHLAGIANA BAVARICA GROWING IN A DRY WALL.

in the country there are a hundred garden Roses, and yet I suppose that without the exhibition Rose and all that it means, the garden Rose as we know it to-day would have been *non est*, and so may they long continue. The one is a complement of the other, and there is plenty of room for both, not only in our gardens, but in our hearts. I remember a certain morning this last June I found myself confronted with the old problem, "Which is the most beautiful Rose?" brought back for reconsideration and a fresh judgment by a particularly beautiful flower of Mrs. Foley Hobbs. It had been coming slowly to perfection for a week, and here it was "at its best," as near perfect as one can expect, a four-point bloom meet to compete for the medal for the best bloom at any show. There can be nothing much more beautiful in the

British Queen and Simplicity. Then that vast host that one cannot label with one colour name—rather whose colours have no name: Queen Mary (a really lovely Rose), Carme, Lady Pirie, Theresa, Mrs. Herbert Straker, Old Gold, Mrs. F. W. Vanderbilt, Margaret Molyneux, Sunbeam, Florence Edith Coulthwaite, Mme. C. Lutaud and Irish Fireflame. And from the bedders one passes to the semi-climbers and climbing varieties. Would there were a few more perpetual-flowering Roses among them! They are coming, no doubt, but very slowly. One welcomed this year Danæe and Moonlight; but they are not climbers, hardly semi-climbers. They have the continuous-flowering habit, for their raiser has shown them consistently throughout the season, and never better than at the autumn show, where I was very glad to see

Moonlight obtained a gold medal; but I must return to my subject. Among the wickrarians, Diabolo, Francois Juranville, Dr. Van Fleet, Gerbe Rose and Shower of Gold have been better this year than I ever remember to have before seen them. Of the ramblers or stronger growers: American Pillar, Bush Rambler, Evangeline, Goldfinch (particularly good) and Tausendschön. This latter has made 15-feet to 20-feet shoots with me, and the tints of the young foliage add a charm to the plants. The flowers last a very long time, although it really only flowers once. The semi-climbers or pillar Roses: Nothing very new has been brought to my notice, but Sarah Bernhardt, Johanna Sebas, and Crêpuscule have been very fine, and Lady Waterlow and Trier are two indispensables. Of the climbing sports, Souvenir de Pierre Notting has been magnificent, is still full of flower, and far and away the best yellow climber we have. The flowers have lost a lot of the rough outer petals that spoil the dwarf form, and have been the colour of Maréchal Niel. Climbing Richmond has also come to stay, and Climbing White Maman Cochet promises to be very good and useful.

HERBERT E. MOLYNEUX,
Southampton.

ROSES OF RECENT INTRODUCTION.

WHILE the Rose season, which is now only too manifestly on the decline, was—chiefly through lack of moisture—not too favourable for what may be termed a profusion of Roses, it was, on the other hand, in Southern Scotland at least, creative of quality in an eminent degree. This was chiefly owing to the abundant sunshine, of which, I believe, we had more in Scotland than even in the southernmost English counties. The varieties that were finest in our Scottish gardens were undoubtedly the Teas and Hybrid Teas. I have never seen Anna Olivier, for example, with such a depth of colour as it had this year. It was quite as rich as apricot in my own garden as its derivative (Lady Roberts) at its finest, and that is saying much. I have for many years regarded the latter beautiful Rose as best adapted for the conservatory; it is not too reliable in our variable climate when grown in the open air. But the loveliest Roses I had this season were, for the most part, of quite recent introduction. I had not, unfortunately, the privilege of seeing British Queen, for this was one of the very few varieties of any reputation that during last winter succumbed to the frost. I presume that I had assigned it too exposed a situation; but it was from the first anything but a vigorous or reliable specimen, and I hope to obtain a stronger representative of this phenomenal Rose from its raiser this year. But, on the other hand, such truly superb Roses as Mrs. Charles Hunter, from Lin-

luned Waltham Cross, surely one of Messrs. William Paul and Sons' very finest creations; the exquisitely-tinted Duchess of Sutherland, a variety from Newtownards well worthy of its name; Abes de Rothschild, a hybrid Maréchal Niel, one of the most beautiful and richly fragrant yellow Roses in cultivation; and such distinguished varieties from Portadown in Ireland as Countess of Gosford, Miss Amy Hammond, Ethel Malcolm, Evelyn Damtesey (after the style of the incomparable La France), Mrs. Alfred Tate (of quite unique colour, one of whose derivatives is probably Old Gold), the highly distinctive Dorothy Ratcliffe and, above all, Mrs. Herbert Stevens (one of the most perfectly-formed and refinedly-textured pure white Roses that ever were raised), have proved

THE DECORATIVE DAHLIA KAISERIN AUGUSTA VICTORIA PLANTED FOR EFFECT.

during the past season so memorable for the marvellous beauty of their flowers—invaluable acquisitions. Lady Hillingdon, though exquisite at the nurseries of Messrs. Thomas Smith and Sons in this county, accomplished nothing during the summer in my garden; but towards the end of the season it made a visible effort in the direction of floral production, though its flowers are lamentably lacking in size. Meanwhile I am looking forward to the first appearance here next season of three Hybrid Teas of the greatest fascination, viz., George Dickson, British Queen and King George V.

DAVID R. WILLIAMSON.
*Manx of Kirkcubbin, by Drummore,
Wigtownshire*

THE FLOWER GARDEN.

DAHLIAS FOR GARDEN EFFECT.

IN years gone by the Dahlia was looked upon as an almost indispensable autumn flower, but now we often hear the opinion expressed that Dahlias are almost useless for colour effect in the garden. The reason is not far to seek, for the older varieties of the decorative class hold their heads of bloom on stout stems well above the foliage, whereas most of the modern varieties introduced under the name and disguise of improved sorts possess the unpardonable fault of weakened stems, hiding their heads of bloom beneath a dense green

mass of growth and foliage.

Happily, some of the older varieties good for garden colour-schemes are still to be obtained, while the new Paony-flowered race bids fair when better known to outrival the old show Dahlia for massing. Readers should be wary of the alleged improved varieties as seen at exhibitions. More often than not these flowers are either displayed in show boxes or with stems stiffened by wires. Such varieties may be utterly useless from a garden point of view, however excellent they may be for exhibition. Now, by thoughtfully choosing the right varieties, it is possible to create truly wonderful autumn colour-schemes with Dahlias. It needs only a glance at the accompanying illustration to make this point clear. Here is seen a bed of the variety Kaiserin Augusta Victoria, in which the flower-heads are borne on stout stems well above the foliage. This bed is situated near the lake at Kew, and from all directions the white flowers show up clearly, and make a bright and telling spot upon an autumn landscape. It is true that many of the flowers are semi-double, and from a florist's point of view they may be lacking in form, but for producing a mass of bloom this variety has few equals. It is unfortunate that there are two varieties bearing the name Kaiserin Augusta Victoria, and the one here referred to is not the Paony-flowered variety, but a pure white decorative Dahlia that grows from 2 feet to 3 feet in height,

and one which is becoming very popular for colour effect, is Délice, a sturdy grower with delightfully fresh pink flowers. It has this year been seen in many gardens, and, having rendered a good account of itself, it has doubtless come to stay. Loveliness is another charming variety. It is now flowering to perfection in a border of autumn flowers at Gimmershury. It goes without saying that self colours give the most pleasing effect, particularly when massed in great numbers.

The single and Pompon Dahlias look very dainty in the garden, and are deserving of more attention. The same may be said of the little-known bedding varieties, of which Flora Macdonald (yellow),

Rising Sun (scarlet) and King of the Dwarfs (purple) are among the best. These varieties seldom exceed 2 feet in height, and are very useful in gardens of limited space. Of the Cactus varieties, Ames Perry (scarlet) and Garden Yellow are two of the very best. Nor must we omit Mauve Queen, Conquest (crimson) and the dark form of the old favourite J. H. Jackson.

TREES AND SHRUBS.

A BEAUTIFUL SNOWBERRY.

UNDER the name of *Symphoricarpos mollis* and *S. occidentalis* a large fruited Snowberry has been fairly frequently exhibited at the fortnightly shows of the Royal Horticultural Society in autumn for three or four years past. On October 11, 1910, as *S. mollis*, it was given an award of merit, and on Tuesday of last week a first-class certificate. Considerable difference of opinion exists as to the correctness of the nomenclature. It has been conclusively proved to be neither of the species named, but a large-fruited form of the common Snowberry (*S. racemosus*). Raisers of new and improved varieties of plants can readily understand how this large-fruited form has been obtained—by raising seedlings from the largest fruits through several generations and growing the bushes in rich soil. Both species, *S. mollis* and *S. occidentalis*, are now in cultivation at Kew; but neither can in any way compare with the specimen illustrated, this being an infinitely better plant in every way for garden decoration. The name *Symphoricarpos racemosus macrocarpa* has been suggested for the plant, but no doubt the name *S. occidentalis* will cling to it for some years in nurseries. Present appearances suggest that neither *S. mollis* nor *S. occidentalis* are sufficiently ornamental to warrant their general culture outside botanic gardens. *S. racemosus macrocarpa* is a free-growing bush up to 6 feet in height, with large, pure snow white berries borne in terminal and axillary clusters at the ends of the shoots, particularly those of vigorous growth. These panicles are so heavily clothed with fruits that their weight causes the shoots to arch over, giving the bushes a very graceful appearance. Shown from the famous collection of trees at Aldenham it has aroused great interest and admiration.

The Snowberries thrive in most soils, and are of great value for shrubby borders. In addition to increase by seeds, the bushes produce suckers freely, so that division of the clumps is possible every few years, or pieces may be taken off the sides without lifting the whole specimen. A second useful species, popularly known as the Coral Berry (*S. orbiculatus*), is in cultivation. Of this there is a very pretty variegated form named *folius variegatus*. The *Symphoricarpuses* are natives of North America.

TWELVE USEFUL SHRUBS FOR WALLS.

The selection of suitable shrubs for covering walls is often a perplexing business to persons who are not intimately acquainted with shrub-life, more particularly when neat-growing plants are required rather than the more free and rampant climbers. With this in view, the following twelve kinds have been selected as a guide to intending planters. Plants of strictly climbing habit have been avoided in most instances, and preference has been given to those which are not generally hardy, or which give better results against a wall than when planted in the open. As a rule, any of the plants mentioned succeed quite well with no further attention than an annual pruning as soon as the flowers are over and occasionally nailing the branches into position.

hardy in Cornwall, requires the shelter of a wall round London. The small oval leaves stamp it as distinct from the other species. *T. lanceolata* or *hexapetala* (which is sometimes also called *Cunodendron hookerianum*), while its white, fringed flowers are also very different from those of the other plant. It gives the best results in a sunny position.

Escallonia macrantha. Although this is perfectly hardy in the southern maritime counties, it requires wall culture in most parts of the country, and is an excellent plant for the purpose. Its dark, evergreen leaves are interesting at all seasons, while its deep rose or light red flowers make it particularly showy in summer. It thrives in a variety of soils and situations.

Myrtus communis.—This, the common Myrtle, is always a popular plant in gardens, but many people neglect it by reason of its liability to injury

A BEAUTIFUL SNOWBERRY, *SYMPHORICARPUS RACEMOSUS MACROCARPA*, ALSO KNOWN AS *S. OCCIDENTALIS* AND *S. MOLLIS*.

Plagianthus Lyallii.—This is a New Zealand shrub belonging to the Hibiscus family. It attains a height of quite 12 feet, and may be relied upon to cover a considerable area. It produces clusters of pendulous, white flowers from the leaf-axils in July, and is a general favourite with all who see it. South, west or east aspects are suitable, and warm, loamy soil is required.

Sophora viciifolia. A spiny-branched shrub from China, is quite hardy in the South, but flowers most satisfactorily when planted against a wall in the colder parts of the country. The deciduous, pinnate leaves are composed of tiny, delicate leaflets, and the white, violet-marked, pea-shaped flowers are borne freely in short racemes from axillary growths.

Tricuspidaria dependens.—This is an interesting and decorative evergreen, which, although

in winter. Planted against a wall, however, it escapes injury, and the full value of its rich green, fragrant foliage is apparent throughout the year, while its white flowers are an additional attraction towards the end of the summer. After a warm summer a good crop of black fruits may be expected.

Cotoneaster horizontalis is an excellent plant for a corner. Although when growing in the open ground it rarely exceeds 18 inches in height, it grows quite 10 feet high against a wall, and requires no nailing after it has once obtained a start. Its bright scarlet fruits are very attractive, while the leaves colour brilliantly before they fall in the autumn.

Ceanothus veitchianus.—This Californian evergreen is essentially a plant for a wall. Of vigorous growth, it must be planted in a permanent position

A. O.

when quite small, and if possible from a pot, for it transplants badly. The small, evergreen leaves make it attractive when not in flower, while the blue flowers are borne in such profusion in May as to hide the leaves.

Ceanothus rigidus makes an excellent companion plant for the last named. It is a native of the same country, and is distinguished by its more rigid branches and deeper-coloured blossoms. Like the previous plant, it blossoms with the greatest freedom. Both kinds thrive in well-drained, light, loamy soil, and give the best results when exposed to full sun. They must not be given very rich soil, or the flowering will suffer.

Pyracantha angustifolia.—This Chinese plant was originally called *Cotoneaster angustifolia*, but is now included in *Pyracantha*. Its long, narrow leaves resemble those of the common *Pyracantha* in shape, but have a greyish hue. The fruits are orange-coloured, and ripen during the autumn. A sunny position and light, loamy soil are essential to success.

Coroeka Cotoneaster, a New Zealand shrub belonging to the *Cornus* family, though rarely met

NEW AND RARE PLANTS.

FIRST-CLASS CERTIFICATE.

Symphoricarpus racemosus macrocarpa.—See illustration and note on page 527.

AWARDS OF MERIT.

Helianthus speciosus (Tithonia).—This was by far the most remarkable novelty exhibited at the last meeting, and as such excited much admiration. Strictly speaking, however, it is not a novelty at all, the plant having been introduced from Mexico so long ago as 1833, and is figured in the *Botanical Magazine*, t. 3295. The flower-heads are about four inches across, the florets coloured a crimson-scarlet on the upper surface and chrome yellow below; peduncles single-headed. Of annual duration only, and probably easily raised from seeds. From Mr. W. Batchelor, Towcester.

Nerine Giantess.—This fine variety is said to have been obtained by crossing *N. Bowdenii* and *N. cornucans*, and there are abundant evidences to this end. The tall scapes and large open flowers are very suggestive of the first named, the latter being revealed in the form of the sepals and colour. It is of rose-cerise colouring.

Carnation Queen Alexandra.—A fine pink-flowered sport from *Scarlet Glow*, the flowers of shapely form and supported on strong stems. The variety possesses a pleasing, if not powerful, fragrance. From Mr. Clarke, March.

Dahlia General de Sonis (Collarette).—Florets rich scarlet, the few inner florets being coloured yellow.

Dahlia Carl Bechstadt (Collarette).—A very showy variety of scarlet and yellow colouring.

Dahlia Offenbach (Decorative).—A fine yellow self of much merit. These three were exhibited by Mr. J. B. Riding, Chingford.

Dahlia The Quaker (Cactus).—The florets are finely incurved, and coloured for the most part a pinky white. From Messrs. J. Stredwick and Sons, St. Leonards-on-Sea.

The above-named Dahlias, having been adjudicated upon by a joint committee of the National Dahlia Society and the floral committee of the Royal Horticultural Society, carry the first-class certificate of the former and the award of merit of the latter.

NEW ORCHIDS.

FIRST-CLASS CERTIFICATE.

Cattleya Adula Glebe Variety (C. bicolor × C. hardyana).—This is an exceptionally fine form, with deep rose sepals and petals tinged with red, while the broad lip is purplish crimson. Shown by G. C. Phillips, Esq., Sevenoaks.

AWARDS OF MERIT.

Brasso-Cattleya Iris (C. Iris × B.-C. Thorntonii).—A charming acquisition to this class of Orchid, with rosy purple sepals and petals, while the large round fimbriated lip is crimson-purple with a yellow throat. From Messrs. J. and A. McBean, Cooksbridge, Sussex.

Cattleya Fabia Prince of Wales (C. aurea × C. labiata).—One of the best forms seen. It has purplish sepals and petals and a ruby crimson lip, with yellow lines in the throat. Exhibited by Messrs. Sander and Sons, St. Albans.

Odontoglossum crawshayanum superbum (O. Hallii × O. harryanum).—This variety has yellow sepals and petals with dark chocolate-coloured markings, while the large open lip is white, with purple spots at the base around the yellow crest.

NEW APPLES.

FIRST-CLASS CERTIFICATE.

Guelph.—A very handsome, highly-coloured and richly-flavoured variety. Parentage: Charles Ross × Rival. The fruits resemble the former parent in colour and flavour, but are larger in size. A deputation of the fruit committee were very favourably impressed with this Apple as seen upon the tree at Newbury. See illustration.

AWARDS OF MERIT.

Peacemaker.—In colour, form and size this variety closely resembles the former, but its fruits ripen quite a fortnight earlier. Parentage: Houblon × Rival. These two varieties were raised by that successful and veteran raiser Mr. Charles Ross, and were shown by Mr. W. Pope, Welford Park, Newbury.

Cliveden Prolific.—This variety, of medium size, possesses excellent cooking qualities; moreover, it is a very heavy cropper. It is claimed to be a poor man's Apple, as it crops heavily in good and bad seasons alike. Shown by Mr. W. Camm, Cliveden Gardens, Taplow.

The foregoing were all shown before the Royal Horticultural Society on October 7, when the awards were made.

THE NEW APPLE GUELPH (MUCH REDUCED), WHICH GAINED THE ROYAL HORTICULTURAL SOCIETY'S FIRST-CLASS CERTIFICATE RECENTLY.

with in gardens, is a decidedly handsome plant when grown against a south or west wall. Its tiny, dark bronzy green leaves, with a grey reverse, remain in good condition throughout the year, while in June its golden, star-shaped flowers are a great attraction. Light, loamy soil is suitable.

Hydrangea petiolaris is strictly a climbing plant, its branches ascending and clinging to their support by means of aerial roots, as in the case of the Ivy. It is an excellent plant for almost any position where an evergreen is not necessary. The flowers appear in large heads, many fertile flowers being accompanied by a few sterile blooms. The blossoming-time is summer. It is a native of Japan.

Cydonia japonica cardinalis is a very rich coloured form of the common *Cydonia*, or *Pyrus*, *japonica*. Of vigorous habit, it will grow 15 feet or 18 feet high if allowed. By keeping the breast-wood cut back, a spur-like condition of the branches is encouraged, from which the maximum number of flowers may be expected. A sunny position is desirable. D.

Nerine Glory of Sarmia.—A very handsome variety with flowers of crimson-scarlet. These two came from Messrs. Barr and Sons, Covent Garden, W.C.

Nerine Salmon Queen.—The name is descriptive. The variety is an exceedingly handsome one, tall and imposing in stature, and bearing a fine head of flowers.

Tricyrtis stolonifera.—The Toad Lilies are remarkable for their quaintly-coloured flowers, and this is no exception to the rule. The above appears to be possessed of a more branching habit than some, the copiously-spotted flowers more bell-shaped in outline. These two came from Mr. H. J. Elwes, Colesborne.

Paulownia tomentosa lanata.—This handsome foliage plant was well shown by the Hon. Vicary Gibbs, Elstree, and for its leaf-growth is well worthy of cultivation. The flowers of the newcomer are said to be coloured violet.

Carnation Yellow Stone.—The flowers are of good size, pale yellow in colour, with occasional touches of palest primrose. From Messrs. Allwood Brothers, Hayward's Heath.

GARDENING FOR BEGINNERS.

HOW TO PLANT BUSH FRUITS AND APPLES AND PEARS.

IN small gardens use must be made of every square foot of ground. Some cultivators utilise every square inch, practically reaping good crops of various kinds and, also, a lot of enjoyment out of the necessary work. Not very long ago we were accustomed to see one or two very large Apple, Pear or Cherry trees in a small garden. Few such specimens remain; they had to give place to smaller ones representing several varieties in the same space, and in the modern garden the small tree has been, and rightly so, the first consideration of the cultivator. I am now dealing with such trees.

The Rooting Medium.—This is a very important matter, and must receive first attention. Unlike an annual or a plant in a pot, the fruit tree must remain in the same position for a number of years, and so we must thoroughly prepare the soil. Trench it 2 feet 6 inches deep at least. The subsoil must be well broken, but left below; all top soil—which is the best—should be left there. Where the trees or bushes are planted in rows, side by side, covering any considerable area, the whole of the ground must be trenched. For a single row of them, trench a space 7 feet 6 inches wide. For a standard or one bush or pyramid, trench a space 8 feet across. For bush fruits, only half the spaces denoted above will suffice.

Position.—Then, of course, there is the position to be considered, not only for the fruit trees, but also for ordinary vegetables and flowers. Fruit trees certainly need some shelter from north-east and south-west winds. Low sheltering fences or walls, which break the force of the wind without unduly obstructing air and light, are the best. Then, it follows that the fruit trees must have a position to their advantage without any dis-

HOW TO PLANT BUSH FRUITS. THE DIAGRAMS ARE FULLY EXPLAINED IN THE TEXT.

advantage to other crops. Rows of tall-growing trees should always be planted on the south side of a broad path, as then the shadow they cast falls on the path, and not on the crops on the

other side. Black Currants do well in a cool quarter.

How to Plant the Trees and Bushes.—I will first deal with Black, Red and White Currants, and Raspberries and Gooseberries. Fig. A shows at No. 1 a young Black Currant; No. 2, a Gooseberry, the two thin, lower shoots of which must be removed; No. 3, a Red or White Currant. No. 4 shows a rooted Black Currant cutting; the buds, *a, a*, must be retained. No. 5 shows a Red Currant cutting; the basal or stem buds, *b, b*, must be picked out, also any showing on the stems of White Currants or Gooseberries. No. 6 shows a weakly Raspberry cane, and No. 7 a strong one; after cutting off the tiny sucker, *a*, plant such a cane. These few hints will be useful as regards the preparation of bush fruits for planting. The distance apart from bush to bush when forming plantations is shown at No. 8. Raspberries—single plants—must be 18 inches apart; and if planted to form clumps of three or five canes, in rows 4 feet 6 inches asunder, as shown respectively at No. 9.

Apples and Pears.—Fig. B at No. 1 shows how to plant and stake a standard tree, and No. 2 how to fix the tying material. Nos. 3 and 4 show a bush Apple and a pyramid Pear respectively after planting. No. 5 depicts how to fix a wire trellis for espalier trees; No. 6 how to train single cordons on low walls; and No. 7 how to train the branches of a fan-shaped specimen on a wall. No. 8 represents a cordon trained on low wires near a path, and No. 9 a double, upright cordon. The latter furnishes wall pillars very nicely. Plant firmly while the soil is pretty dry, and rake the latter firm around the roots.

G. G.

PLANTING STANDARD, BUSH AND CORDON APPLES AND PEARS.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Flower Garden.

Gladioli.—As the foliage becomes matted, these should be lifted, spreading them out in a frame, shed, or some other dry place till they can be cleaned out, afterwards storing them in a cool, dry place for the winter.

Montbretias.—In some localities these will stand the winter quite well in the borders; but in cold, damp situations it is wise to lift and treat them much in the same way as Gladioli; but, the bulbs being smaller, they will not stand the same amount of drying.

Begonias that were lifted from the beds should now be in a dry enough condition to warrant their being cleaned over, removing the old shoots carefully and all loose soil, when they also should be stored in boxes or trays in a dry shed that is not too warm.

Cannas I have found grow best if they are not allowed to get too dry during the winter. Remove all the decaying foliage from the plants that have been lifted, when they may be stored in a cool, dry house with a little light soil or leaves among the roots. I have also brought them through the winter very successfully in an ordinary cold frame well protected with dry leaves.

The Pleasure Grounds.

Good, Deep Trenching is most essential where shrubs are to be planted, as rarely can the soil be moved much afterwards. Very poor soils should be enriched with some good loam, peat, leaf-soil, or manure, according to the nature of the shrubs that are to occupy the ground, though fairly good and holding loam rarely needs much enriching for ordinary shrubs.

Planting.—It is still early for planting, but there is no need to delay it after the soil has got wet enough to allow the plants to come up with good balls of soil, early-planted shrubs having by far the best chance of going through the following summer without ill-effects.

Plants Under Glass.

Specimen Plants, such as Bougainvilleas, Clerodendrons and Allamandas, may be removed for the winter months to a cool house; in fact, a resting fruit-house is a very good place in which to winter them.

Roof Climbers, wherever possible, should be shortened back or tied in, so as to admit as much light as possible to the plants underneath, and in many instances water need only be given now in very sparing quantities, so as to rest the plants as far as possible.

Fuchsias.—Old plants that are to be kept over for another season should now be in a fit condition for storing, and if there is not room to store them in a cool, dry greenhouse, any old shed where frost can be entirely excluded will do for them, dry straw placed among the pots and among the wood often making them quite secure, where, if not covered, they might get the frost during a very severe spell.

Young Plants that may be growing on through the winter to make specimens should be very carefully watered, or, if the temperature happens to be rather high, the growth will become soft and attenuated, and this is not desirable.

Freesias.—The early-potted plants are now growing freely, and if they are wanted in flower by Christmas, they must be given just a little heat. A very light and warm frame will suit them well, but a shelf in a rather warm greenhouse will probably keep the foliage a little harder and stronger. Stake as soon as required, for once the growth goes down, distorted flower-spikes are the result.

Chrysanthemums will need a fair amount of attention just now, and all damped petals must be removed before they affect others near them. Fire-heat now is quite essential at night, and where the blooms are near the ventilators, till any stretched above them will possibly prevent a good deal of trouble from damping. Avoid draughts through the house as much as possible, as I believe more blooms are lost from this cause than from any other, so restrict the front ventilation during damp or foggy weather.

The Kitchen Garden.

Carrots.—Growing crops in frames should have the lights put on at night now, as a sharp frost would practically stop their growth, and providing there is the faintest suspicion of warmth in the bed, they will continue growing for some little time yet. Matured roots should be kept drier, as even small Carrots will be found to split if given too much water after their growth is practically finished.

Mint that may have been grown on in boxes as advised in an early calendar may now be introduced into heat in sufficient quantity to keep up a supply, and if it has been allowed to get rather dry, I find it comes along fairly quickly after a soaking or two of water, and once it gets a start, liquid manure-water is a distinct advantage.

Hardy Fruit.

In every garden where a quantity of fruit is grown there is each season a proportion of the trees that would be benefited by a change of position. Certain varieties may not do well in the position they are in, which, if shifted, say, on to higher ground or, maybe, on to lighter soil, might prove highly remunerative, so that wherever trees are found to be doing badly and which have been root-pruned with a view to improving their cropping qualities, they might well be given another chance.

Trees Planted in Heavy, Wet Soils often do very badly, particularly Pears, and in one instance I noted, after they were lifted bodily and planted from 6 inches to a foot higher out of the ground, the trees commenced to give good, clean crops, and the inference drawn from this is that under such conditions trees cannot well be planted too near the surface.

Preparation of Ground for Planting.—Here again I would emphasise the necessity of thoroughly preparing the ground before planting, either by trenching deeply the whole of the ground in the case of planting in the garden, or, if for orchard culture, breaking up really good stations for them, in no case less than from 8 feet to 10 feet across. It may not be necessary to add manure to the soil; rather add old mortar rubble, leaf-soil, or anything of a lightening nature on close, retentive soil, and good loam or a proportion of clay, well incorporated, into soils that are too light.

FOR NORTHERN GARDENS.

The Flower Garden.

Lifting and Storing Dahlias.—These showy autumn flowers cannot be expected to do duty much longer, and must soon be lifted and stored. A dry day should be selected for the work. Cut the plants down to within 6 inches of the ground and lift carefully with a digging fork.

Spring Bedding.—There is nothing to be gained, but rather the contrary, by delaying this work longer. Clear away the summer bedders and give the beds or borders a dressing of half-decayed manure. Dig deeply, leaving a nice smooth surface. Last year, in a geometrical design of twenty beds here, fourteen of them were planted with Royal Blue Forget-me-not, and the remainder (fairly large beds) were filled with three varieties of Wallflower, and so pleasing was the effect that we are going to repeat the arrangement this year.

The Rose Garden.

Firming Plants.—The more vigorous varieties of Roses are often a good deal knocked about by the autumn winds, and upon close examination it will be found that they have been loosened at the neck. The whole stock should be gone over, and any plants which have thus suffered should be firming with the foot, the plant being held in position by one hand meanwhile.

The Rock Garden.

Building. Unless one is dealing with a natural slope furnished with loamy soil, the surface should, before building commences, be covered with from 6 inches to 12 inches of soil of the nature indicated. Where height is desired and a natural slope does not exist, part of the desired height should be obtained by means of excavation, the excavated soil being

thrown up some distance above the ground-level on either side. By this means moisture will be largely conserved and less watering required.

The Pleasure Grounds.

Sanding Lawns.—Of the utility of this operation there can be no doubt, more especially on heavy soils. It furnishes a free root-run for the finer grasses, checks the growth of moss, and makes it more easy to maintain a perfectly smooth surface. The sand should be scattered over the surface as evenly as possible by the hand, and the lawn should afterwards be gone over with a new Birch broom to further ensure the proper dispersal of the sand.

Gravelling Walks.—Walks requiring fresh gravel should have attention in the autumn in preference to spring, for several reasons; Work is not so pressing at this season, everything should be done to make things look fresh and bright during the dull days of winter, and, by attending to the work now, the walks will be cleaner and drier during wet winter weather.

Plants Under Glass.

Deciduous Calanthes.—These beautiful terrestrial Orchids will now be showing colour, and should enjoy a fairly warm temperature with rather dry conditions both at the root and in the atmosphere, otherwise damping is sure to take place. These flowers always seem to look their best when associated with Ferns.

Perpetual-Flowering Carnations.—Whenever the temperature falls below 15°, a little fire-heat should be applied. Air should be given when the weather is at all fine, but not during fog, as it tends to curl up the blooms. If good blooms are expected, disbudding must be attended to as these develop.

Fruits Under Glass.

Guavas.—Although not fit to be classed among first-class fruits, still, these West Indian fruits commend themselves to some tastes. Where the Vines are allowed ample room, Guavas succeed very well on the back wall of ainery. They must have a thoroughly well-drained soil, which should chiefly consist of sandy fibrous loam with an admixture of leaf-mould and dried cow-manure.

Pot Fruits.—Any of these which have not yet gone to rest will be benefited by an application of weak liquid manure to assist in the process of swelling the buds. As the trees naturally go to rest, however, water should be more sparingly applied.

The Hardy Fruit Garden.

Replanting.—The trouble generally, with Apples and Pears especially, is not so much to get them to grow as to throw them into and maintain them in a fruiting condition; in other words, to induce the trees to produce fewer wood-buds and more fruit-buds. A fortnight ago I referred to root-pruning as one means of attaining the desired end. Another means is that of lifting the trees and replanting them. The check to the trees consequent upon this operation generally has the desired effect, and marvellous results have sometimes been obtained by this means with trees which have been barren for years. Some cultivators invariably lift and replant their young trees after they have made their first year's growth.

The Vegetable Garden.

Cauliflowers.—In many districts sharp frosts are often experienced about this season. When such is the case, all Cauliflowers fit for use should be lifted and stored in a cellar. They can either be laid in among soil or hung up head downwards. I heard the other day of the latter method succeeding well in a disused ice-house.

Celery.—Continue to earth-up the crop as necessary, and when the final earthing is given, finish off with a smooth, sloping surface, so as to carry off the winter rains as far as possible.

Asparagus.—As soon as the grass has died down, cut it over and clear it away, remembering that it forms a good protection for beds of bulbous plants which are barely hardy. After removing any remaining weeds, give a liberal dressing of half-rotted farmyard manure and fork it in with the digging fork.

Lifting Rhubarb Stools.—It is found that Rhubarb responds more readily to forcing when the stools have been lifted for some time and exposed to the clemency of the weather.

CHARLES COMFORT.

Broomfield Gardens, Davidson's Mains, Midlothian.

NURSERY NOTES.

MESSRS. H. MERRYWEATHER AND SONS.

acres planted with standard trees of this Apple a few years ago, the work being entrusted to Messrs. Merryweather, and it is one of the finest examples of orchard planting that we have ever seen. If the Development Commissioners desire a lesson in orchard planting, they should visit Southwell and see this orchard, which is rapidly growing into a most valuable asset. In addition to the ordinary Branley's Seedling, Messrs. Merryweather now have a form of it with red fruits, which ought to prove particularly useful for market.

The Merryweather Damson, of which we published a coloured plate in our issue of October 22, 1910, is a fruit that ought to be in every garden. We were privileged to see the original tree in the nurseries at Southwell, and it was simply laden with rich-coloured fruits, many of which were as large as Orleans Plum. When we say that it has the true Damson flavour and that the trees fruit well in quite a young state, we think it will be admitted that our statement that it ought to be in every garden is fully justified. Another good fruit that this firm has raised is Red Currant The Southwell. It has a particularly robust habit, flowers late, so as to escape damage by frost, and bears heavy crops of deep red berries, the flavour of which leaves nothing to be desired. In addition to the above, the firm has splendid stocks of all kinds of hardy fruits, including cordon Gooseberries, espalier Apples and Pears, fan-shaped Plums and Peaches, Loganberries, the newer Lowberry, Blackberries and Nuts, and all, at the time of our visit, were in the very pink of condition, sturdy, well-ripened wood auguring well for their success when the trees and bushes are planted in their permanent quarters.

Equally as important a branch of Messrs Merryweather's business is that devoted to Roses. This year they have over two hundred thousand bushes to dispose of, these embracing large quantities of all the best standard sorts as well as the cream of recent introductions. When growing Roses in our gardens, we ought not to forget that it was this firm that first gave us those two gems of the Dwarf Polyantha section, Jessie and Phyllis. When we were at Southwell these were creating a wonderful sight, rows about two hundred yards long being a perfect glow of colour. Jessie has flowers of rich, warm crimson hue, while those of Phyllis are bright rosy pink. Having grown them for several years, we have no hesitation in saying that they are the best of the whole section, for they are never out of flower from early July until October or November frosts call a halt. Another point in their favour is that they do not lose their colour in the strongest sunshine. We would like to see large lawn beds of these Roses. (A circular one some ten yards in diameter, planted fairly thickly in the centre with Jessie and a yard-wide edging of the white-flowered Katherine Zennet, would be most effective, and far better and much more lasting than the bizarre and expensive effects so often obtained by the use of Zonal Pelargoniums and other plants still so dear to the heart of many gardeners. Phyllis, intermixed with Lavender in the proportion of two Rose bushes to one of Lavender, would give a charming and uncommon effect that would, we

WILL TOBACCO PAY IN ENGLAND?

IT is quite within the bounds of possibility that Tobacco-growing will develop into a large industry in this country within a few years. Experiments of a very satisfactory nature have been carried out in Hampshire, Surrey, Norfolk, Suffolk, Lancashire and Worcestershire. About one hundred and thirty acres have this year been laid down by the Tobacco Growers' Society—a non-profit-making co-operative association affiliated to the Agricultural Organisation Society and assisted by grants from the Development Commission. Speaking generally, the crops in the various counties have exceeded expectations; but as the subject is yet in its infancy, it is of little use going into elaborate calculations on yields and averages at this stage. It is suggested that Tobacco will prove to be a poor soil crop. There is a difference of opinion on this point at present, but the plea is that Tobacco is going to do well on the poor light land in Norfolk, Hampshire and Dorset, which at present is of little more than sporting value. Be this as it may, we are undoubtedly handicapped in the question of climatic conditions. It may not be generally known that Tobacco owes its flavour in no small degree to the gum or sticky secretion upon the leaf. As this is formed on the upper side of the leaf, it is only too readily removed by heavy rains. Moreover, the leaves are liable to damage by wind as well as rain. Now, these adverse conditions may be overcome by the modern invention of movable glasshouses. The system has reached a high standard of perfection, and by its use the inventor, Mr. Pullen Bury, Sompting, near Worthing, claims to have solved the problems of Tobacco-growing in this country. The system of movable glasshouses is the outcome of experiments extending over many years, and so admirably has the principle been perfected that the pipes, boiler, wires, ventilating gear, &c., are all moved in one simple operation by turning a handle. Such structures are being very profitably used for the purpose of growing Asparagus and French garden crops, and they afford just the necessary protection to bring the Tobacco leaf to a state of perfection. Our illustration depicts a movable house filled with Tobacco. Mr. Pullen Bury (the figure on the left of the illustration) is seen holding some Tobacco leaves of good but average size. These leaves, it should be noted, have small midribs—an important point in their favour; but the blades of the leaves are well expanded. This is the result of quick growth, brought on under glass, and such leaves are said to give quality and mildness to the Tobacco produced. At the time of our visit to Worthing, Tobacco leaves were seen hanging from the wires inside the hotbouse to wilt while the hotbouse is fulfilling the function of forcing. As already stated, it is as yet too early to say, with any degree of certainty, that Tobacco-growing can be made a paying industry in this country. That it can be induced to flourish there can be no doubt, and if only a tithe of the Tobacco sold in this country could likewise be grown here, it would provide a vast industry.

THERE are few better-known nurseries in the Midland Counties of England than those of Messrs. H. Merryweather and Sons, a firm that has been established for many years at the historical little cathedral town of Southwell, some twenty miles from the city of Nottingham. For gardeners generally, and fruit-growers in particular, these nurseries have a peculiar interest, inasmuch as it was from them that the well-known culinary Apple Branley's Seedling was first put into commerce. For many years Mr. Merryweather, who is the senior partner of the firm, endeavoured, though in many instances unsuccessfully, to induce fruit-growers in many parts of the country to plant this Apple on a large scale. Meanwhile, knowing that he had a variety of sterling merit, he was busy planting all the spare

TOBACCO-GROWING UNDER GLASS. MR. PULLEN BURY, THE INVENTOR OF THE MOVABLE HOTHOUSE SYSTEM, IS SEEN ON THE LEFT OF THE ILLUSTRATION.

land that he had, and the result to-day is that he has orchards of large dimensions filled with beautiful trees that are capable of bearing from ten to twelve bushels of fruit each. During recent years fruit-growers and salesmen have awakened to the possibilities of this Apple, which is in season from Christmas until April, with the result that the demand for trees and fruit all over the country is far in excess of the supply. On a sunny day in September we had the pleasure of spending some time in the nurseries and orchards belonging to the firm, and the trees of this Apple, ranging from five to thirty years of age, were a sight worth going many miles to see. In the gardens in the district one also meets with trees on every hand, one and all bearing enormous crops of fruit second to none for culinary purposes. Not far from the firm's nurseries, Mr. Starkey, the local M.P., had a field of forty

feel sure, so much appreciated by all who saw it. Among Roses of recent introduction we were interested to see good stocks of British Queen, a large, pure white-flowered variety; Kayon d'Or, deep canary yellow and quite mildew-proof; Sunburst, cadmium yellow and perfect in shape; Florence Haswell Vertch, rich crimson, very fragrant; and Mrs. Herbert Stevens, pure white and very useful for florists. Of rather older sorts, but as yet new to many of our readers, mention must be made of Château de Clos Vougeot, deep crimson maroon; Lieutenant Chauve, large crimson, very fragrant; Leslie Holland and Edward Mawley, both crimson; Lady Alice Stanley, pink, shaded glowing rose; and Marquise de Smet, a deep-colored Mme. Ravary, among the Rambler Roses, of which Messrs. Merryweather have a very extensive stock, mention must be made of Excelsa, glowing crimson; Shower of Gold, yellow and very hardy; Lady Godiva, a salmon pink sport from Dorothy Perkins; White Dorothy Perkins, American Pillar and Hiawatha.

In addition to Roses and fruit trees, the firm has a very fine stock of English and Irish Yews, Cypressess and other conifers, Rhododendrons, all sorts of hardy deciduous shrubs, herbaceous plants and, indeed, everything that one would expect to find in well-equipped nurseries of such large dimensions. The healthy condition of this stock and the firm's up-to-date method of business have brought them repeat orders from every corner of the British Isles, as well as from many more distant parts of the globe.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

THE GREENHOUSE.

BLUE HYDRANGEA FLOWERS (Mrs. N. W.).—A shade of blue in Hydrangea flowers such as those sent is not uncommon. In soils containing plenty of iron some of the blooms, if not all, invariably develop the blue tint. It is possible to produce the colour in plants by giving them water in which alum has been dissolved. Another method which is sometimes successful is to mix a few iron filings in the potting soil.

DRYING OFF HIPPEASTRUMS (Dorset).—Do not dry off your Hippeastrums till the leaves turn yellow, but give them plenty of air and sunshine. Then, when the plants show signs of going to rest, less water should be given, and when they are quite dormant it must be discontinued altogether. During winter keep them dry in a temperature of 50° to 60°.

LILIJUM LONGIFLORUM HARRISII (C. B. A.).—In order to have these in flower at Christmas, the most satisfactory way will be to obtain retarded bulbs, which in a temperature of 55° to 65° will flower from twelve to fifteen months from the time of potting. Single bulbs, according to their size, may be grown in 5-inch or 6-inch pots, while three can be put in a pot 6 inches to 7 inches in diameter. When growing they should have a good light position assigned to them, and care must be taken that aphids or green fly do not effect a lodgment in the young leaves, as they soon injure the growing buds. The Bermuda-grown bulbs of Lilium Harrisii will, if potted now, flower during the month of January or later. There is no need to start the bulbs in the dark; just pot them and place them in the greenhouse.

TREATMENT OF CŒLOGYNE CRISTATA (Dorset).—In the spring, as soon as the flowers are over, the plants should be given a short rest by lessening the supply of water, but not sufficient to cause the pseudo-bulbs to shrivel. When young growth recommences, repotting, if necessary, may be done, but the plants take a long time to recover from the shock. For this reason, should the roots be in good condition, top-dressing is generally preferred to repotting. Deep pans are preferable to pots, and a very suitable compost, either for repotting or top-dressing, may be made of equal parts of sphagnum moss and fibrous peat or Osunda fibre, with a sprinkling of small broken crocks and rough silver sand. After this an excess of moisture must be guarded against, though atmospheric moisture set up by occasional spraying, with the damping of the stages and surroundings, will be beneficial. During the winter the roots must be kept moderately moist. At that season a temperature of 50° to 60° will suit it well.

FRUIT GARDEN.

TOMATO DISEASE (K.).—The Tomato is badly nourished. Sulphate of potash should be added to the soil; this will tend to the equal ripening of all parts of the fruit.

PEAR FOR INSPECTION (Reader).—The Pear is overripe and has been attacked by the Pear scab fungus. Prune out during the winter all dead and dying shoots, and spray the tree just as the buds burst, and again after the petals fall, with Bordeaux mixture.

APPLE EMPEROR ALEXANDER GOING BAD (H. Taylor).—This fine-looking Apple should be ripe at the end of September, and is therefore an attraction to wasps and blowflies. We can only suggest that the fruit has been injured by these pests, the injury spreading in the further decay of those parts. The fruit should have been gathered as soon as the decay was noticed. We could have given you a better answer, perhaps, had you sent us a sample of the bad Apples.

TO MAKE WALL TREES BEAR FRUIT (L. A.).—In the first place, we would have the wall pointed so as to do away with the harbour the deep crevices in it afford to insect pests. In the next place, we should lift the trees and replant, after cutting all the strong roots back by one-third their length, and shortening also all the smaller roots by 3 inches or 4 inches. This will prevent the trees growing too luxuriantly, and should compel them to bear fruit. In replanting, use the following soil compost: To one cubit of turfy loam add two bushels of old mortar rubble, two bushels of lime and a peck of bone-meal, mixing all well together. Let the work be done in dry weather, and give the trees a good watering when planting is finished. Fertilise the blossoms on sunny days when the pollen is dry. Take down the clo-netting every day while the weather is favourable, and put it up again in the evening when danger from frost is feared.

KITCHEN GARDEN.

CELERY (J. C. S. C.).—The Celery is badly attacked by the fungus *Septoria petroselinii* Apil, causing the disease known as Celery leaf-spot. This fungus is exceedingly common, we fear, now, and is undoubtedly carried in the seed. Spraying, to be effective, must be commenced in May and carried on through the season, Bordeaux mixture being the best thing to use. All dead pieces and refuse from Celery plants should be burned, and not dug into the ground, and next season a fresh piece of ground should be chosen upon which to plant. The seed should be obtained from a clean source.

MISCELLANEOUS.

SUBSTITUTE FOR NATURAL MANURE (H. P.).—Wakley's Hop Manure is the best substitute that we know for natural manure, although, of course, natural manure is the best where it can be obtained.

GROWTH ON BEECH LEAVES (Hortist).—The curious growth on the Beech leaf is the work of a minute insect, *Hormomyia betulina*, which sets up irritation in the leaf and causes it to produce this curiously-shaped gall. It is rather common on Beech trees in some districts.

CATERPILLAR OF THE VAPOURER MOTH (R. C.).—The caterpillar is that of the vapourer moth. When abundant these caterpillars do a good deal of damage, but are rarely so numerous that spraying has to be resorted to. If they are found in any great numbers, spray the trees with lead arsenate.

CATERPILLARS (H. E. I.).—The caterpillars are those of the type known as surface grubs, which feed on a variety of plants during the night, hiding during the day in the earth, where, from their colour, they are well concealed. Hand-picking is the best remedy, but heaps of bran, poisoned by moistening with Paris green or lead arsenate, placed near the plants might prove attractive to them, to their undoing.

REMAKING GRAVEL PATHS (Scot).—There is nothing to equal good, yellow, binding gravel for the surface of the paths which are to be kept smooth by rolling, and we regret to say that we are unable to recommend any other material of a like character which may be procured in Scotland. Perhaps a local builder may be able to suggest something, or be able to advise you as to the nearest point at which binding gravel may be obtained.

HOLIDAY COTTAGE GARDEN (F. M. J.).—The general outline of the plan will do very well. It does not indicate, however, where you are likely to be overlooked and subjected to the objection of which you complain. This is important, since on the northern and eastern boundaries you have either existing, or you intend planting, both

Elm and Plane trees, and it would be difficult to get plants having screen-like habits to succeed in their proximity. Then, in place of the single line of Roses, which, by the way, are arranged too closely together at the edge of the lawn, a bed or border across its western end would have been better, and in full view from the tent. Good Roses for the pergola would be Lady Gay, Grüss an Teplitz, Sylvia, Tausendschön, Shower of Gold, Céline Forestier and Bordeaux. Free-flowering Roses for the garden should include Caroline Testout, Mme. Abel Chatenay, La France, Marquise de Smet, General Jacqueminot, Prince Camille de Rohan, Château de Clos Vougeot, General Macarthur and Duchess of Albany. Standards are usually available of most of those named, though we think bush plants would be more suitable in your case. The Moss and Cabbage Roses may be had from any Rose-grower. It is rather difficult to recommend plants for the herbaceous borders, and if they are intended to grow under the Elm and Plane, we do not hold out much hope of success. Good plants for the season indicated would include Phloxes, Pentstemons, Hollyhocks, Sunflowers (single and double), Aster acris, A. Anellus, Michaelmas Daisies in variety, Gallardias, *Staticolatifolia*, any of the Japanese Anemones, *Helianthum pumilum*, *H. p. magnificum* and *H. cupreum*.

NAMES OF FRUIT.—Mrs. C. P. B.—1, Wellington; 2, Bramley's Seedling; 3, Allington; 4, Lord Grosvenor; 5, Lord Suffield; 6, Ribston Pippin; 7, Blenheim Orange; 8, Cox's Orange Pippin; 10, Cobham Pippin; 11, Warner's King; 12, Cellini; 14, Hawthornden; 22, Emperor Alexander; 23, King of the Pippins; 20, Hall Door; 21, Allington; 24, Queen Caroline; 25, Gloria Mundi; 15, Mank's Codlin; 16, Bismarck; 17, Alfriston; 26, Cellini; 19, Lane's Prince Albert.—Constant Reader, Perthshire. 1, Lord Derby; 2, Queen Caroline; 3 and 4, Kedleston Pippin.

NAMES OF PLANTS.—Harold Oslee.—Laurent Carle.—D. D. D.—We believe the Rose is Mme. Pol Varin Bernier; certainly it is not Alice Graham.—Lieut. Colonel H. F. Dent.—We believe the Rose is correctly named. Roses vary greatly at this season of the year.—A. K. Burnshangie.—All seedling forms of Aster Novi-Belzti.—Mrs. B. Sutherland.—*Rhacomitrium canescens*. It may be grown on damp rocks.—F. C. B.—The Clematis may be *C. Flammula*, but we cannot be certain without seeing flowers.—Miss H. B.—*Collinsia bicolor*.—Madame.—1, *Carex brunnea variegata*; 2, *Begonia metallica*; 3, *B. fulcioides*; 4, *Aloe species*; 5, *Adiantum pulverulentum*; 6, *Nephrolepis Piersonii* variety; 7, *Adiantum formosum*; 8, *Selaginella Brancii*; 9, *Xiphidium molle*; 10 and 11, No specimen; 12, *Poly-podium aureum*; 16, *Asplenium species*.—A. P. Sussex.—1, *Aster ericoides* variety; 2, *Chrysanthemum uliginosum*; 3, *Linaria Cymbalaria*; 4, *Colutea arborescens* (Bladder Senna); 5, Cannot name without flowers.—J. E. L.—1, *Crumm* species probably (cannot name without flowers); 2, *Hieracium aurantiacum*; 3, *Colchicum speciosum*; 4, *Cattleya bicolor*; 5, *Escaellonia macrantha*; 6, *Osmantha Aquifolium*; 7, *Phillyrea media*.—R. T. H.—1, *Helixine Solierii*; 2 and 3, cannot name without flowers.

THE EDITOR'S TABLE.

Pentstemons from Scotland.—The arrival of a box containing numerous spikes of Pentstemon blooms serves to remind us of the great value of these showy flowers even late in the season. The flowers came from Messrs. John Forbes of Hawick, who have long specialised in Pentstemons and various other border plants. Of the varieties sent we were much impressed by those of dark crimson shades, of which Grigor, Mendel and Colonel Seely may be cited as examples. Of the scarlet varieties Professor Pozzi stood out conspicuously, while Lady Hamilton and Comte Zeppelin were notable for their plum red hues and very strong growth. The more delicate tints of Mrs. Oliver, Jessie Forbes, Sir William Carrington and others are particularly pleasing when used as cut flowers for room decoration.

Gladioli from Dorset.—Very fine indeed were the massive spikes of Gladioli which arrived with the following note from Mr. F. Lausdell of Inglewood Nursery, West Moors, Dorset: "I am sending you a few blooms of Gladioli for your table. Princeps (the crimson one) is a glorious sight when planted in clumps of eight to twelve corns. It is not so well known as the pink one (America), but is far more effective for border work than that variety. White America seems the favourite for shop work. Another sterling variety is Halley, as large in bloom and spike as princeps, but of a salmon colour. Unfortunately, this is over, and I was unable to send you a spike."

EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

NOTES OF THE WEEK.

The National Sweet Pea Society.—The annual general meeting of the members of this society was held at the Hotel Windsor, Victoria Street, Westminster, on Monday afternoon last. A report of the proceedings, which were of an animated character, appears on another page.

Orders for Rose and Fruit Trees.—Owing to the exceptionally mild weather, Roses and fruit trees are still growing freely, and in many nurseries it is impossible to start hitting them. Under the circumstances, we hope that those of our readers who have placed orders with advertisers will not press for early delivery.

Lifting Begonias. The first touch of frost will finish off these tender plants for the season. Lift them carefully and store them away in a cool place where they will be immune from frost. It is a good plan to place a little dry soil in the bottom of shallow boxes and place the tubers in these thickly, one deep, with the crown upwards. Treated thus, the percentage of loss is very small.

A Graceful Knotweed (*Polygonum equisetiforme*).—This little-known Knotweed is specially noteworthy as an autumn-flowering subject for the rock garden. The plant is of broom-like appearance, of low, branching habit. The dark green stems are dotted with small white starry flowers, which are both showy and welcome in October. This *Polygonum* is well adapted for planting among high rocks, so that the low, arching sprays may hang down and partly clothe the boulders.

An October-flowering Saxifrage.—In a sheltered nook in the rock garden or along the front of a shrubbery border the panicles of white flowers of *Saxifraga Fortunei* are delightful in late autumn. This year, if anything, the plants are flowering better than usual, the mild weather and warm rains being, no doubt, responsible for this. The panicles of flowers rise out of tufts of dark green, rounded leaves to a height of from 15 inches to 18 inches. The white flowers are very freely borne on the comparatively large spreading panicles. An interesting botanical character is the unequal size of the petals. *Fortune's Saxifrage* is a native of Japan.

Planting Lily of the Valley.—The Lily of the Valley is quite a universal favourite, and few gardens exist where this well-known plant does not find a home; but to keep up a good supply of first-rate blooms a new bed should be formed every three or four years, either by freshly planting an old bed or by new plants obtained. The present time will be found the most suitable for the operation, selecting a half-shady, moist place in not too prominent a position, for the ground is bare a good deal of the year. Should the soil be too light, some good loam with decayed manure should be worked into the soil; but if, on the other hand, it should be too heavy and damp, dig it out to a depth of 2 feet, putting in 6 inches of drainage. On the top of this lay some peat sods or turfy loam,

then replace some of the soil after mixing with it some leaf-soil and dry cow-manure. Put the roots in 2 inches deep and 4 inches apart and good mulching afterwards will be found very beneficial.

An Interesting Tropical Fruit.—A plant of *Eugenia alba* growing in a pot in one of the side-stages in the Palm House at Kew is causing considerable interest among the visitors by reason of its uncommon-looking fruits. Perhaps the easiest way to describe these fruits is to liken them to the white sugar Pears hung on a Christmas tree. They are borne in clusters, generally of three to five, at the ends of the branches. The waxy white fruits are 1½ inches long and 1 inch wide. The *Eugenias* in general habit and flowers resemble the Myrtles, the popular *Myrtus Lima* being sometimes cultivated as *Eugenia Lima*, notably in Ireland. *E. alba* is a native of India.

Mexican Tree Flowering at Kew.—The beauty of the Mexican flora is well illustrated by a tree of *Pachira macrocarpa* flowering in the great Palm House at Kew. The tree has been at Kew since 1877, and evidently delights in the moist tropical conditions of the house, as it is about sixty feet in height, reaching to the central dome. A very handsome and attractive malvaceous tree, the leaves resemble those of the Horse Chestnut, being digitate, with usually nine leaflets. The flowers are large, with very long white, reflexed petals, in the centre of which are a mass of stamens of a reddish hue and as long as the petals. The tree is said to have been first introduced from Mexico in 1849, and is figured in the *Botanical Magazine*, t. 4549.

"Sporting" of Lilies.—At a recent meeting of the scientific committee of the Royal Horticultural Society, Mr. C. R. Searse-Dickins showed a most interesting series of specimens of *Lilium Sargentiae*. A bulb had last year produced a stem, part of which carried the foliage of *L. Sargentiae*, part foliage similar to that of *L. myriophyllum*. This plant was grown from a bulb, not from seed. This season offsets from it bore respectively foliage similar to that of *L. Sargentiae*, *L. myriophyllum*, and partly of the one, partly of the other. The flowers were indistinguishable. It would seem that Mr. Searse-Dickins had seen the passage of one species of Lily into another, or that the breadth of foliage which is constantly used as a distinguishing feature of these plants is a character of less importance than it is usually considered. Mr. Elwes drew attention to the remarkable variation to be seen between Lilies as one passes up the Formosa Mountains, as, though one species had produced forms adapted to the conditions under which they were growing and regarded by botanists who had seen only collected plants as specifically distinct, other characters in plants which had been used by herbarium botanists as a basis of classification were frequently variations of adaptation as seen in the field.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

The Campanulas.—It will probably be more convenient for me to deal with the different points raised in correspondence about the Campanulas when the articles are concluded, rather than to discuss them in a desultory fashion. I am glad to see the remarks of Mr. Farrer and Mr. Jenkins on different species. They will help to elucidate questions which arise in connection with several of the smaller and also the larger Bellflowers.—S. ARNOTT.

Rose Peace for Cool Conservatories.—I possess a small plant of this, a rooted cutting from a very fine specimen growing in a cool structure somewhat shaded by Fir and other kinds of trees. My plant, about one foot high, nicely branched already, has borne one nice bloom and now carries another bud. The parent tree covers a roof space of about one hundred square feet. Another

by Mr. Hugh Dickson, who received a gold medal for it.—E. M.

Name of Fungus.—In last week's issue of THE GARDEN Miss Jekyll asks for the name of a fungus growing under Scotch Firs. From her description I have little doubt that it is one of the two species of Sparassis. They both bear a considerable resemblance to a large bath sponge, and are very brittle in texture. Sparassis crispa is not uncommon on sandy soil in the South of England, usually under Firs or among Heather. S. lammosa occurs more rarely in similar situations, but is a looser-growing plant altogether. It was first recorded in Britain in 1905, when it was found in Wodmer Forest, and a very fine specimen was found there this autumn on the occasion of the British Mycological Society's visit to that district. Both species are well figured in "Fungi and How to Know Them," by E. W. Swanton. Although superficially bearing a slight resemblance to a morel, Sparassis belongs to a totally different group of fungi, *i.e.*, the Clavariaceae, of which the

and autumn and *not* caught queens? (3) Any other successful traps? (4) How to manipulate your conservatory or your stoke-hole, *i.e.*, after W. W. Richardson, so as to find a lot ready to be killed at each visit.—W. F. M. COPELAND. [We shall be pleased to publish particulars dealing with the points raised by our correspondent if readers will kindly send them.—ED.]

Rock Garden Plants in October.—The very interesting note on this subject which appeared in last week's issue, page 525, will be read with appreciation by lovers of alpine flowers, as it serves to show that the rock garden may be made beautiful with flowers at this season as well as in the spring and summer. I was pleased to note the prominence given to that rare Milfoil or Yarrow, *Achillea Kellereri*, which induces me to send a photograph of it as it now appears in a Surrey garden. It is a delightful little plant, with heads of white flowers freely disposed over its silvery grey foliage. This plant is named in honour of Herr Kellerer, a lynx-eyed collector of mountain flowers, who has charge of the King of Bulgaria's garden at Sofia.—C. Q.

Nerines.—The article on Nerines by Mr. H. J. Elwes in your issue of September 13 was such an important horticultural event that I trust it attracted the attention to which it was certainly entitled. As a painstaking student of Nerines for some years, I acknowledge that it was most useful and helpful to me, especially as it cleared up several points as to which I have been in doubt. Like Mr. Elwes, I am much puzzled to know why the Nerine is not in more general cultivation. Its flowers are so charming, the colours so beautiful and sparkling under artificial light, and its requirements so few, that it would be well if some of the amateurs who now devote the whole of their glasshouses in autumn to Chrysanthemums could be induced to take it up, or at any rate let them devote part of their Chrysanthemum space to it. Its only enemy is mealy bug, which Mr. Elwes explains how to combat, and in other respects it is probably one of the most easily-cultivated under-glass bulbs that one grows, especially as it

only needs repotting once in three years at the most. I agree in the main with Mr. Elwes' standards of a good Nerine, but I think he should have given a good spike more consideration. In looking round the Royal Horticultural Society's Show at Vincent Square on October 7 I noticed a number of what I call loose-petalled flowers. I like to see a spike that stands erect, its pips evenly distributed and a look of solid substance about it, such as was evidenced in Mr. Elwes' Salmon Queen, which gained an award of merit. Snowflake, of which Mr. Elwes speaks in his article, was, as shown by him on the above date, a distinct disappointment to me. It was decidedly tinted pale flesh colour, and not at all one's idea of what a pure white Nerine should be. Speaking again of Salmon Queen, it seemed, as I saw it, to bear a most remarkable resemblance to *Rotherside*, of which I put five fine plants before the Royal Horticultural Society's floral committee a month ago. I believe the two varieties to be identical.—F. HERBERT CHAPMAN, *Rotherside Gardens, Rye.*

AN OCTOBER-FLOWERING ALPINE: *ACHILLEA KELLERERI*.

recently-rooted cutting has made much growth and now forms a fine bush in a pot, bearing flowers on ninety per cent. of its shoots. The old plant has flowers on it nearly the whole year round. The blooms are of medium size, soft yellow in colour, and borne on stiff stems. They look charming in vases. Amateur cultivators should have a plant in their greenhouse or conservatory, as it is such a lovely and satisfactory variety to grow.—G. G.

Rose Lady Pirrie.—If I were confined to one dwarf Rose in the garden, I think I should choose the above, for it possesses all the attributes found in any variety. In growth it is vigorous, having stiff, erect stems, with handsome dark leaves, which continue to give blossoms all the summer and well into the autumn. The peduncle is stiff, thus holding up its flowers quite erect, which is a distinct point when employing them for vases. Its colour is deep coppery reddish salmon, the inside of the petals apricot yellow, flushed fawn and copper. It is an ideal variety for massing, also as a delicious perfume. It was sent out in 1910

pretty little white and yellow fairy-clubs are the most familiar examples. The spores are produced exposed to the air from the first, whereas in the morels and allied fungi the spores are enclosed in flask-like sacs, only opening at the apex at maturity.—NORMAN G. HADDEN, *St. Audreys, Priory Road, Malvern.*

The War on Wasps.—I was much interested to read W. W. Richardson's remarks on the war on wasps in your issue of the 18th inst., especially as a recent correspondent in a contemporary stated he had frequently caught lots of queen wasps in the ordinary wasp bottles, both in the spring and autumn. Do you think, Sir, that some organised plan or method could be put forward for the destruction of these pests? Would you encourage readers of your paper to write and tell something of their methods as to catching queen wasps, both in the spring and autumn? (1) How to successfully organise a prize for the greatest number caught locally. (2) Do queen wasps *really* enter the ordinary wasp bottles, as the writer has set them both in the spring, summer

Rose Mrs. James Lynas.—The illustration on page 516, October 11 issue, of this new Rose portrays the variety to perfection. I have three plants of it and all have given me numerous flowers; in fact, it is the best new Rose of the year with me. Every bloom, no matter how small, has been of perfect shape. The petals are especially massive without being coarse or ill-shapen, which gives the blooms such a handsome appearance. I expect to see this Rose universally grown before long.—E. M.

Lilac Flowering in October.—It would be interesting to know if any of your readers have seen a Lilac in blossom in October. The enclosed flower is off a good-sized tree of the ordinary kind growing in a garden here. It is not in a sheltered position. There are quite a number of blossoms out and plenty of buds, which, if the frost keeps off and the weather continues mild, will no doubt open. The flowers smell as sweetly as they do in the spring.—RUTH B. CANNON, *Painswick, Gloucestershire.*

An Unusual Flower-Bed Arrangement.—Walking along a neighbouring road the other day, I happened to notice some flower-beds in front of a house, the hedge next the road being rather low. Among them was one bed somewhat unique, I venture to think, for its colours puzzled me for the moment until I had a closer look. The plants then turned out to be a *Heliotrope* of a deep blue colour and *Diplacus* or *Mimulus glutinosus*. The blue flowers of the former mingling among the coppery shade of the latter was most arresting and pleasing. I have never seen the blending of these plants in any other garden or park, though it is well worthy of being copied, I am convinced.—C. T., *Highgate.*

Are New Pentstemons Too Large?—I note the paragraph on page 494, and do not agree with Mr. Bernard Crisp. If Mr. Crisp is wedded to such forms as *Newbury Gem* (syn. *Hartwegii*), then I do not wonder at his dislike of the newer florists' varieties, for which Mr. Forbes of Hawick has long been noted. I have grown the new varieties sent out by Mr. Forbes annually for the last ten years, and it was but last week I remarked "I have not seen any increase in the size of the flowers for several years now. Pentstemons have evidently reached their limit in size." For the embellishment of the garden in bed, border, or in lines of one sort, I think the superior forms of newer sorts have a distinct and increasing future before them. Take, for example, the variety *George Home*, bright scarlet, with a pure white throat, or some of the more recently improved forms of this raised by Mr. E. Beckett at Aldenham, and what more impressive sight of colour could we have in the garden? Flowers of this type have reasonably large bells, which expose the two colours, scarlet and white, to perfection; whereas in the case of *P. Newbury Gem* and its varieties they are lacking in colour and decision.—M. E.

The Charm of Michaelmas Daisies.—Those who grow these flowers only among the ordinary herbaceous plants can have no conception of their beauty and individuality when seen growing together in a mass, each variety given sufficient space for perfect development, as upon this so much depends to show each variety off to its fullest extent. Take the variety the Hon. Edith Gibbs, for example, which is a seedling from *Aster ericoides elegans* crossed with *Robert Parker*, a form of *Novi-Belgii*. This grows 5 feet high, throwing out side shoots within a foot of the ground. Each of these shoots right up to the point is smothered

with its pale blue blossoms, making a perfectly-formed, drooping specimen right to the ground. When such varieties as these are huddled together with the ordinary herbaceous plant, no conception is possible of the natural beauty of the finest of Michaelmas Daisies. In years gone by, when we had no other forms but those of *Novæ-Angliæ*, like *pukhellus*, for instance, with its trusses of flower quite at the top of 6-foot shoots, there was no harm in crowding such at the back of the herbaceous border, if it were only to hide their gaunt-looking stems. Just one more mention of another sort, *St. Egwin*. When well grown this runs up a yard high and is almost as much through, a full, rounded head of rich rose colour that seems to require space to show off its richness and beauty which it undoubtedly possesses.—M. S.

Rose Fortune's Yellow.—I was much interested in Mr. Harriss' article on that most beautiful and desirable Rose, *Fortune's Yellow*, as grown at Lockinge, and am reminded of a very interesting discussion on the same subject which appeared in the pages of *THE GARDEN* a few years ago. My knowledge of this Rose extends now for nearly two decades, and I am at one with Mr. Harriss in nearly all he says respecting its cultivation, differing only slightly in detail. A tree here is restricted to the long span of a hip-spanned greenhouse 24 feet by 12 feet, and the pruning and training is similar to that practised at Lockinge. Here are the differences in detail: Whereas the trees at Lockinge are planted inside, the tree referred to here is planted outside and trained through the wall, much the same as one would train a Vine, and I am inclined to think that this is the ideal way to grow *Fortune's Yellow* Rose. Permit me to add weight to this statement. Let us take growth first. I have referred to the tree here being restricted to the long span of the hip-spanned structure. So exuberant is the growth that it would in one season cover all the roof space if permitted to do so. This state of affairs is entirely free from any extra attention on our part, as feeding and watering is not practised during the growing season, the rampant growth being sufficient to hold our hands in this respect. One more item—we are entirely immune from mildew, and why we are so appears very obvious. Next comes colour. Mr. Harriss gives the blooms at Lockinge as a "beautiful apricot." Describing the colour here, I will do it this way: Let your readers refer to the coloured plate in your special and most excellent Rose issue, take the two half-expanded blooms of *Irish Fireflame*, add a dash of the carmine of *Queen Mary*, and the colour of most of the blooms as produced here is given to a nicety. It may be of some interest to mention that this particular tree is some thirty years old, and 2,000 blooms have been cut from it in one season. It is on its own roots, and the circumference of the stem a foot from the ground-level is 11½ inches. The rooting medium may be described as being neither light nor heavy, and chalk enters into the composition, but not largely. Feeding commences only so soon as the flower-buds begin to show, and continues throughout the flowering period. There is really nothing better as food than that recommended by Mr. Harriss—liquid manure from the farmyard. Reverting to the colour of the blooms of *Fortune's Yellow*, so intense have these been, and yellow appearing such a misnomer, that we feel constrained to refer to the Rose as *Fortune's Rose*, or its synonym, *Beauty of Glazenwood*.—J. McCALLUM, *Buckham Gardens, Alton, Hants.*

OCTOBER IN GARDEN AND WOODLAND.

OCTOBER—the Poet's Month—replete with charm and beauty—the beauty of peace and restfulness, the charm of unexpected surprises, cold nights succeeded by warm, balmy days with bursts of hot sunshine, yet make the flowers think that summer may yet come back again—that fills the bees with work, that brings the Mushrooms up, and swells the later Blackberries, that hang so large and plentifully this year upon the tops of the hedges like bunches of wild Grapes:

" . . . there is a harmony
In autumn, and a lustre in its sky,
Which thro' the summer is not heard or seen,
As if it could not be, as if it had not been!"

Looking across the great weald the Oaks have hardly changed—only the quivering Birch trees from the hilltops stand here and there, flinging from them golden spray. The ripe Walnuts, the orchards full of fruit, all express "Autumn's ripe maturity." There is a calm on all lifeless things—the calm of decay, the silence of farewell,

"The moist rich smell of rotting leaves,"

and a warm, grey mist that connects "the landscape with the quiet of the sky."

In the garden the stillness and silent mystery of October is only broken by the Chestnuts pattering to the ground, the hum of the threshing-machines at work close by, and occasional outbursts of the robin's song. One day we wake to find the world completely shrouded in a thick white pall, through which we can only just descry "the favourite hamlet faint and pale." Nature likes to draw a semi-lucent covering about her handiwork—without rush or hurry in a beautiful quiet routine she fulfils her will.

Birth, the rapturous awakening of love, death, and the strange movement of spring in every twig and hedgerow flower, the return of the swallows, the cuckoo's note upon its rightful day, the fields that are suddenly filled with the bleatings of lambs; at a certain date the Spanish Irises are all in bloom, the Cowslips awaken in the field, rich blossomings quite suddenly fill our Rose gardens and summer beds, the song of the watched-for nightingale at the self-same date; we know that Nature will tell the wild white Cherry to loosen its mass of trembling flowers—such mysteries are not for us.

As the mist rolls gradually away and the low sunshine throws long shadows across the lawns, and on "the silvery dews that drench the Furze," we hear

"The autumn leaves like light footfalls of spirits passing," and we feel a presence has passed unseen, unheard, along the garden path. The Vine has changed to a lovely primrose yellow, the monstrous *Pæony Dahlias* droop their heads, and the *Heliotrope* says good-bye.

So sweet, so calm, should death be to all—not death, but a passing, through strange mysteries, to another life. The flowers are not dead—but after the "slumber of the year" will awaken to fresh life with the first touch of spring. M. C. S.

FORTHCOMING EVENTS.

October 28.—Southampton Autumn Show (two days).

October 29.—Kent County Chrysanthemum Show (two days). Borough of Croydon Show (two days).

October 30.—Torquay Flower Show. Maidenhead Chrysanthemum and Fruit Show.

THE CAMPANULAS OR BELLFLOWERS.

(Continued from page 524.)

C. Saxifraga.—*C. tridentata* Saxifraga of gardens, and mentioned under *C. tridentata*.

C. Scheuchzeri.—Practically a form of *C. rotundifolia* when in gardens, but with woolly leaves and blue flowers in June and July; white in the variety *alba*. Any soil.

C. Scouleri.—A North-West American species, a foot high, and with panicles of pale blue flowers in late summer. Level rockwork. Not, I think, in commerce.

C. speciosa.—A biennial limestone plant, a foot high, with a spike of large, bell-shaped flowers of pale purple. Ordinary soil. Seeds. June or July.

C. Stansfieldi.—A gem among the hybrids. From a close tuft of yellowish leaves rise big lilac blue and half-pendulous blooms in July. An easy plant for the moraine, wall, or flat terrace in the rock garden. Spreads well. Division.

C. stenocodon.—Scarce and rather difficult. After the style of *C. pusilla*, but with narrow, deep blue bells. Should be tried in the moraine, but not yet fully tested. July.

C. Steveni.—Becoming very popular on account of its dwarf variety *nana*, this Bellflower has a future before it. It has narrow, glossy leaves in a carpet, and nodding blue bells in June and July. *Alba* is white, and *nana* is a lovely 6-inch-high blue variety. Division or seeds. Avoid wet at the neck of the plants in winter.

C. thyrsoides.—An old, yellow-flowered biennial, loving a dry place in sun. Rather coarse in its way, with its big head of flowers. Sow in June and grow on. Flowers in June and July.

C. tommasiniana.—A scarce little bushy plant adorned in July with narrow bells of light purple or blue. Slugs are troublesome. Moraine or gritty soil in the rock garden. Seeds or division.

C. trichopoda.—A dwarf species with pale blue flowers and about six inches or nine inches high. Moraine or dry parts of the rockery. Division or seeds, but rare and expensive. June.

C. tridentata.—This is a gem with a charming tufted growth and large flowers of violet blue or purple. It is closely akin to *C. Saxifraga*, it is not the same. Moraine or ordinary rock garden light soil with grit. Seeds or division. June.

C. triflora.—Hardly, if at all, distinguishable from *C. portenschlagiana*, this requires the same treatment. Increased by division and seed where obtainable.

C. turbinata.—Referred to under *C. carpatica*.

C. tyrolensis or **tirolensis.**—This comes near to *C. caespitosa*, and needs the same treatment.

C. uniflora.—A scarce and difficult plant, like *C. excelsa* in its aspect and best in the moraine. Division. June and July until August.

C. valdensis.—There are two forms of *C. valdensis* in cultivation, one with downy leaves and blue bells after the type of *C. rotundifolia*, but narrow; the other with the flowers constricted like a soda-water bottle, lighter blue than those of the above, and the plant of dwarfer habit, between *C. rotundifolia* and *C. caespitosa*. Crevices of the stones of the moraine. Division or seeds. July.

C. velutina. See *C. lanata*.

C. waldsteiniana.—A gem for the moraine or rock garden in gritty soil. Only a few inches high, with dainty, starry flowers of pale blue in June. Crevices or level parts of rockwork or the moraine. Seeds or division. Sun.

C. Zoysii.—But for slugs this would be a favourite everywhere. It is of elegant, rather trailing growth, and in June produces charmingly-shaped, light blue flowers above tufted foliage. Gritty soil or the moraine. S. ARNOTT.

(To be continued.)

THE GREENHOUSE.

THE PERSIAN CYCLAMEN AS A BIENNIAL.

AFTER numerous experiments during the last twenty-five years, I have proved, to my own

CAMPANULA THYRSOIDEA, AN OLD BIENNIAL SPECIES THAT IS NOT WELL KNOWN.

satisfaction at all events, that by far the best results with this grand plant are to be had by treating it as a biennial. I am aware that numbers of good gardeners disagree with this, holding that it is impossible to have really fine plants by this method. I am satisfied in my own mind, however, that with proper treatment quite large plants can be had in beautiful bloom fifteen or sixteen months after the seeds are sown. These easily beat the best old plants for size and substance of flower, while they also bloom for a longer period. Being very successful with this almost indispensable winter and spring flowering plant, perhaps a few notes on how I manage to obtain these satisfactory results may be of interest to others who admire the Persian Cyclamen.

Sowing the Seed.—In most cases seeds are sown at too late a date. Numbers of seed catalogues

say that from October to March is the proper time. This may be well enough where a house can be devoted entirely to this plant, but for ordinary mixed culture it is much too late. I have always had the best results by sowing from August 9 to 15.

How to Sow.—Select fairly deep and perfectly clean seed-pans, those about nine inches in diameter being very handy. Crock with great care, and place some of the rough riddings from the soil over the drainage. The soil should be a nice light, but fairly substantial mixture of three parts fibrous loam, one part flaky peat, one and a-half parts sweet leaf-mould, and one part rather coarse, sharp sand. The addition of about half a part of crushed charcoal is a great help, as it keeps the compost sweet. Pass all through a half-inch riddle and mix thoroughly. Fill the pans to within about an inch of the tops, and make moderately firm and quite level. Scatter the seeds very thinly and evenly, and press down gently with a flat piece of board. Sieve a little of the soil and cover to a depth of about an eighth of an inch. Water carefully either by plunging in a bucket of tepid water or by using a very fine rose on the watering-can. Cover each pan with a sheet of glass, and the glass with thick brown paper or damp moss. Place in an intermediate temperature, and in about three weeks' time the first of the seedlings will be peeping through.

Winter Treatment.—As soon as growth appears, remove the paper, but shade carefully from all sunshine. After all the seeds have germinated, gradually remove the glass and get the pans set up on a shelf quite close to the root glass. Here they should be kept all the winter, attending to them very carefully with water, but also taking care not to sour the soil by too frequent applications.

Pricking Off.—It is a mistake to attempt this too soon. Experience has shown me that February is early enough, and by then each little plant should have four leaves. Two-inch pots should be used, and these should be crocked with three or four small pieces of charcoal. A mixture similar to that advised for seed-sowing is suitable. Pot lightly and leave half of the little bulb above the surface, water, and return to the same temperature, shading carefully. Sprinkle gently overhead twice daily from the time of pricking off until September.

Spring Treatment.—As growth starts in earnest, remove to a slightly lower temperature, and when the little pots are fairly well filled with roots (they must not be pot-bound), shift into larger pots. The very strongest may be allowed the 4-inch size, the others 3-inch or 3½-inch, according to strength. Use much the same compost, only a little more peat may be given, also a 5-inch potful of bone-meal and the same of Ichthemic Guano to the barrow-load of soil. Again pot lightly.

Subsequent Treatment.—As the weather improves, admit air in increased volume and pay great attention to watering. Shade from all sunshine is imperative, as is the sprinkling overhead. Some good growers advise removing the plants to a cold frame during the summer; but, personally, I prefer a greenhouse stage. Tomatoes on the roof, not too thickly planted, afford the proper shade, and under these conditions the plants are always under the eye and thrive beautifully.

The Final Potting.—For the strongest plants provide perfectly clean 6-inch pots. For the medium specimens the 5½-inch size, and for the weaker ones 5-inch pots are best. The soil should consist of three parts best fibrous loam, two parts best fibrous brown peat, one and a-half parts of sweet, flaky leaf-mould, and sufficient coarse sand to keep all sweet. Crushed charcoal may with advantage be added, while a 6-inch potful of bonemeal and a 5-inch potful of Thomson's Plant Manure or Ichthemic Guano must be allowed to each barrow-load of the other ingredients. Use in a fairly rough state, as the idea is to provide a nice "springy" compost. Crock the pots with extra care and agam pot lightly, keeping the bulbs half their depth out of the soil. Water carefully and keep rather close for a few days. As soon as the pots are well filled with roots, feed about twice a week with weak liquid manure and soot-water. A tablespoonful of Ichthemic Guano in a gallon of water is one of the best stimulants it is possible to have for the Cyclamen. Vaporise with XI. All Insecticide occasionally to keep down green fly and thrip, and in due course a fine display will be the reward for any little trouble incurred. Grow a first-rate strain like Sutton's Giant or Sutton's Prize. C. BLAIR

Preston Gardens, Linthgow.

FLOWER GARDEN.

TULIP NOTES.

Some Early Varieties for Pots.

A prod from the Editor has made me once more put pen to paper to blurb, before it is too late, my promise of a few "tips" for the great Tulip-time of 1914. For those who like to have a few "choceries" and "out-of-the-wayities," let me suggest the purchase of Enchantress, a sort of pale ruby red with a blush edge; and Hector, a massive orange and yellow bloom with a strange dullness all over it, which at one time attracts and at another makes one wonder if one does like it or not. Then there is Jenny—among Tulips what Mother of Pearl is among Sweet Peas—the sweetest, brightest, cheeriest little mortal that anyone could wish for as a companion, so *chic* in shape and of such a taking shade of cherry red in colour. De Wet I remember seeing at the Jubilee Exhibition at Haarlem as a new thing. Ever since I have been wondering when it would be obtainable. I believe it can be procured now, for I know it is in the wholesale list of M. van Waveren and Sons of Hillegom, and if so, then the probability is that some retail firms are cataloguing it but I am unable to say who they are. I have an idea that it is a sport from Prince of Austria, as it resembles that variety in everything but colour, which under glass is a real orange shade. In the open the colour breaks into its constituents and it is a mass of red suffused with yellow, which is wonderfully effective for room decoration, for, although I have not as yet grown it myself, I saw what an admirable cut flower it made at the "Woman's Work" Exhibition this year at Amsterdam, where on the day I visited the show it was used to decorate one of the furniture exhibits. Rose Tendre is a flower

of the Cottage Maid type of colouring, but not so dumpty in habit or of such a pronounced pink. I like its pale shade very much indeed, and I rather think that in my pink and white trials this year it will be very near the top when the class list is made out next spring.

Tulip Trials at Wisley.—Before these notes are in print the Tulip-lovers of Britain and Holland will have been, I hope, gratified by seeing the announcement in the gardening papers that the Royal Horticultural Society are going to tackle the question of nomenclature. I trust that something will now be done to settle the question of synonyms, and that, when once these are sorted out and classed under the different varieties to which they belong, amateurs and dealers will accept the result as an *ex cathedra* pronouncement, promulgated indeed by the Royal Horticultural Society, but virtually threshed out and settled (if it is as it is intended) by a

A Dickson and Sons), and to all others, as they say, whom it may concern, to weigh carefully the propriety or otherwise of giving new fancy names to the broken Darwins or to the broken anything else. Let me put the case in a concrete form. A, B, C and D each has a bed of Mr. Furncombe Saunders. In each one a certain number "break"—that is, take on their final (?) striped appearance. As things are at present among these *garden* flowers, there is nothing to prevent A calling his "break" Mary, B calling his Jane, C calling his Betsy, and D calling his Anne. If these A, B, C and D were all traders and went in for increasing their stock until they could offer it to the public, it is quite possible to have the very same thing on the market under all these different names. Not so with the *show* Tulip. Once a Sir Joseph Paxton, *always and for ever* a "Paxton." The breeder form may be grown in fifty beds, and in fifty beds it may break, but no real Tulip man ever thinks of it as anything

CAMPANULA STANSFIELDI, A BEAUTIFUL HYBRID WITH LILAC BLUE FLOWERS.

congregation of the combined wisdom of the Netherlands and the British Isles. After then, should any firm, small or great, or any private person, known or unknown, lay down a false scent, "let them or him be anathema." It is atrocious to go and rename any variety for no reason except, presumably, that of selling both it and its purchaser. I have been told that once upon a time Bishop Magee of Peterborough had some sauce spilt on his episcopal coat at a dinner-party. He looked up and down the table with a bland but imploring look, and said: "Will some layman make an appropriate remark?" How often have I—how often have those who read these lines—planted some newly-found treasure, only at flowering-time to wish that that layman was at our side?

One thing I would like to see done, and I appeal to my friends Mr. Krelage, Mr. Leak (of Messrs. R. H. Bath), Mr. Hugh Dickson (of Messrs.

but Sir Joseph Paxton; he simply calls it "Sir Joseph Paxton flamed" or "Sir Joseph Paxton feathered," or he could equally correctly say "Sir Joseph Paxton broken." The old Tulip men went through all the bitter and provoking time of a haphazard and lawless nomenclature sixty and more years ago, and the principle now *universally* adopted among the show growers of to-day is one born of a long-drawn-out experience as being at once truthful, simple and speaking. I sincerely hope this question of naming "breaks" will occupy the attention of those who are called upon to form the nomenclature committee, and that the very much threatened tangle of names of the beautiful striped varieties will not be allowed to mature.

JOSEPH JACOB.

[We should be pleased to hear the views of Messrs. Krelage, Leak and Hugh Dickson on the naming of Tulip breaks.—ED.]

A LITTLE-KNOWN TORCH LILY.

(KNIPHOFIA TYSONII)

This handsome South African plant does not seem to differ in any way from *Kniphofia caulescens*, except that it flowers at a different time, the latter flowering during June, whereas the subject of this note flowers during August and September. Apart from its flowers, which are orange red, fading to pale yellow, its handsome, glaucous blue foliage would merit it a place in the garden, and, as the illustration shows, it is a handsome subject for a lawn bed. A large group of it, suitably placed, is very effective in a large rock garden, and on a sloping bank it is likely to get the right conditions to come through the winter safely, while damp and stagnant moisture often prove fatal during winter.

Although *K. Tysonii* likes dry conditions during winter, care must be taken that it does not suffer from drought during the summer, as, in common with other members of this

lavender, with rose flakes; Blondin, pale blue; Cassandra, pale lavender blue; Lilacina, pale blue, shaded lilac; Mme. de Beauharnais, rich dark blue; Mont Blanc, pure white; Surprise and Zulu, rich purplish red; and Miss Barclay, white, with violet markings.

Westwick Gardens, Norwich. E. G. DAVISON.

HYBRID LILIES.

Owing to the prominent position of their floral organs, it might be thought that hybrid Lilies would be plentiful. Such, however, is not the case, for there seems a strange fatality about some of the best-marked kinds; for instance, that gorgeous hybrid raised on the other side of the Atlantic between *Lilium auratum* and *L. speciosum*, and known as *L. Parkmannii*, has quite disappeared. It was given a first-class certificate by our Royal Horticultural Society in 1880, and was shown occasionally for some years afterwards, but it is now no longer to be found. Its first appearance

COLOURED PLATE.

PLATE 1479.

A NEW CULINARY APPLE.

It is not often that a new culinary Apple shown before the fruit and vegetable committee of the Royal Horticultural Society possesses sufficiently good features to secure an award of merit; hence it is worth placing on record any that do gain this coveted distinction. The variety of which a coloured plate is given with this issue is named Padnall Seedling, and was raised by Mr. Roberts of Padnall Hall, Chadwell Heath, Essex. When shown by him last year at the Royal Horticultural Society's meeting at the end of August, it received an award of merit, a deputation from the society having previously visited the trees and reported upon them to the committee. Subsequently we visited Mr. Roberts, who kindly showed us the original tree and also a number of young ones that had been recently grafted. The habit of the tree is robust, and the foliage very large and tough, reminding one greatly in that respect of Peasgood's Nonsuch, but the fruits themselves more resemble Warner's King. They are large and crisp, of good flavour, and in season from early July until mid-September. We regard this as a good and useful addition to the early culinary Apples, and as the young trees, when grafted on Paradise stock, fruit well in their early stages, it should prove a useful variety for planting in private gardens where space is limited.

A HANDSOME TORCH LILY OR RED-HOT POKER: KNIPHOFIA TYSONII.

genus, it enjoys copious supplies of water at the root during the growing and flowering season. As with most *Kniphofias*, this plant is not likely to prove over-hardy in cold districts, but a little dry litter placed round the plants should bring them safely through most winters. J. C.

ENGLISH IRISES.

This section of a large family is a most useful one, providing us with flowers in July, and by planting good bulbs a fine display of flowers can be relied upon. They succeed in any good soil, and are quite hardy. The flowers are large, and the colours rich and striking. The bulbs should be planted in autumn. September is a good time, although planting may be deferred till December. They may be planted in clumps in the herbaceous borders, or a border may be wholly planted with them. There are many fine varieties to choose from. The following are good forms: Anton,

in this country created quite a *favorite*. That pretty and interesting cross raised at Kew some dozen years or so ago between *L. Henryi* and *L. Brownii* Chloraster, and known as *L. kewense*, seems to have shared the same fate. Crosses between the Chinese *L. Hansonii* and different *Martagons* have good constitutions, and are likely to prove reliable garden Lilies.

There are several hybrids between the upright-flowered Lilies, such as *L. croceum*, *L. davuricum* and *L. elegans*, and also among the North American species of the *Martagon* section. These American-raised forms were distributed as *L. Burbankii*, but they are a mixed race. One Lily, which, by the way, is only a supposed hybrid, is the grandest of all. This is the Nankeen Lily (*L. testaceum*), which is one of the finest outdoor Lilies we have. It is an assumed hybrid between *L. candidum* and *L. chalcedonicum*, but its origin seems to be unknown.

in the South and West maritime counties and in Ireland. In those counties it is found as a large bush, 2 feet to 4 feet high and sometimes 6 feet in diameter, at all times a good evergreen, and during autumn and winter an excellent flowering shrub. The kind and quality of the soil is not of vital importance; providing climatic conditions are suitable, there are few places where it will not thrive. In more northerly counties the various forms are often grown as pot plants for conservatory decoration, and large specimens are cultivated in tubs for terraces and corridors. About London and in the neighbourhood of other cities and towns they are grown in large quantities by nurserymen and sold for planting in window-boxes or for flowering in dwelling-rooms, and they are familiar objects on the stalls and carts of itinerant plant and flower vendors.

Propagation is easily effected by means of cuttings of young shoots inserted in sandy soil in a close frame during spring or summer. The young plants, if placed in a nursery border and stopped

TREES & SHRUBS.

SOME GOOD AUTUMN-FLOWERING SHRUBS.

AMONG the numerous shrubby species of *Veronica*, that known as *V. speciosa* has appealed most widely to the horticulturist, and in his hands numerous varieties have appeared which exhibit an extensive range of colour and in many instances bear larger inflorescences than the type. Being a native of New Zealand, it is not very hardy in the British Isles, but gives excellent results

NEW APPLE PADNALL SEEDLING.

once or twice, develop into shapely little bushes by the end of the first year and usually produce a fair number of inflorescences, but it is not until they are three or four years old that they really do themselves full justice. It usually happens, if attention is paid to pruning during early life, that little is required afterwards, that little being the removal of the old flower-heads as soon as the flowers are over, so that the production of seeds is prevented. Should the old flowers be left, the seed-vessels are somewhat unsightly as they die off. In some parts of Devonshire and Cornwall small plants are inserted in the stone and soil walls which are so popular in those counties. The plants appear to enjoy the position and grow into fine specimens, which bloom profusely. Whether used in that way or in the shrubbery, they are equally desirable, while some people use them very effectively for informal hedges.

The type is well known by reason of its bluish or purplish flowers, which appear in dense racemes 2 inches to 3 inches long. Of the varieties the following are all very beautiful, and well worth attention either for outdoor or pot culture. Blue Gem, a vigorous shrub of dense, compact habit, with large and conspicuous leaves. The blue flowers are at their best during autumn, though a few continue to open during winter. Autumn Glory is another blue-flowered kind. Of fairly compact growth, it is dwarfier than many varieties, and can be used where a large-growing bush would be out of place. Gauntlet. —This is an exceptionally fine variety, producing spikes, 5 inches or 6 inches long, of pretty pinkish flowers. The foliage is large and richly coloured. Mme. Chrétien. —In this variety the flower-spikes are 4 inches to 5 inches long, and are made up of rich purple flowers. La Séduisante is also a vigorous kind; its flowers are reddish purple. Manx Queen is one of the best of the red-flowered kinds, while another one, which was distributed by Mr. Gauntlet a few years ago under the name of Redruth, also bears rich red blossoms. Then there are other varieties, such as Vulcan (dark reddish purple), Snowflake (white), Purple Queen (a dwarf, purple-flowered kind), Mme. Santin (blush), Monte Rose (rose), and Le Merveilleux (rosy purple), which are all very pretty.

CLIMBING PLANTS ON A GARDEN PILLAR.

It often happens that the most pleasing instances of colour associations are the result of accidental planting, and such is the case depicted in the above illustration, taken in Colonel H. Moore's garden at Higher Woodcombe, Minehead, Somerset. Colonel Moore sends the following note: "The garden pillar was formerly clothed with Clematis montana. Solanum crispum has invaded it from the adjoining wall, and as the pale lilac and white flowers make a pretty contrast, I have allowed them to fight it out together."

THE ROSE GARDEN.

IN A HAMPSHIRE GARDEN.

SOME OF THE NEWER ROSES.

(Continued from page 526.)

I MUST now pass on to deal with individual Roses, and, taking the exhibition varieties first of all, one comes to the Hybrid Perpetuals. They have had one, and only one, addition to their ranks this year, and that is

Coronation (Hugh Dickson, 1913), a huge flower that reminds one of the old Her Majesty, but

Coronation is reminiscent of Fran Karl Druschki in its method of growth, but is much more globular in shape, after the style of Mrs. Cornwallis-West in its flowers. Its size will be bound to make it popular with exhibitors. It is the first Hybrid Perpetual to receive the gold medal since Hugh Dickson was awarded it at the Glasgow Show in 1903, ten years ago. I well remember the sensation it caused, but it seems longer ago than ten years somehow. I wonder whether we shall have to wait another ten years for the next Hybrid Perpetual. I rather expect before then that Hybrid Perpetuals, Hybrid Teas and such-like distinctions will be things of the past. Having mentioned Her Majesty in connection with Coronation—the two names are more or less inseparable—I ought to add that Coronation is not so subject to mildew as Her Majesty, if at all.

George Arends (Hunner, 1910) is one of the so-called pink Druschkis. It is scented, but that is the most one can say for it, and I am discarding it this year, as it is not much good for exhibition and we can do without in the garden.

Geoffrey Henslow (Turner, 1912), a dark-coloured crimson that will be contended, I am afraid, with the Rose of the same name, a Hybrid Tea. Of the two I prefer the latter, as it is undoubtedly a better colour and does not "blue" so badly.

Gloire de Chedane Guinoisseau (Guinoisseau, 1907).—I think this Rose has enhanced its reputation. It has been in nearly every winning twenty-four, and has undoubtedly come to stay. Every exhibitor should have it. It is hardly a new Rose, but being raised on the Continent is a severe handicap, and it has taken some time for its merits to be recognised. It is a full flower, well and perfectly formed, of a bright shade of crimson, a good grower, and of the easiest culture. The buds are produced in a cluster of four or five as a rule, and must be disbudded accordingly.

I can think of no more Hybrid Perpetuals that can be called exhibition varieties, and so we come to the Hybrid Teas, the class that seems to rake in all varieties, where we find Roses so unlike in character as Irish Fireflame, Mrs. Andrew Carnegie, Queen Mary, Old Gold and Moonlight all labelled Hybrid Teas. Something will have to be done, and that soon, to remedy this state of confusion. Naturally, everyone is looking to the National Rose Society to suggest a remedy and apply it. Here is a great chance for fame for someone to go down to posterity as the man who revised our Rose classification.

HYBRID TEAS.
Alice Lemon (Hill and Co., 1911).—This stands much where it did, and although I have seen a few flowers of it, it evidently has not got into general cultivation. It is a vigorous grower; colour, flesh, deeper salmon centre; flowers of good pointed shape; not subject to mildew.

British Queen (S. McGrody and Son, 1912) — I have grown this Rose for two years now, so can

CLEMATIS MONTANA AND SOLANUM CRISPUM GROWING TOGETHER ON A GARDEN PILLAR.

slightly brighter in its shade of pink. It promises to give us one of the largest of exhibition flowers. It is very vigorous in growth, tall and erect, and I remember noticing that the wood was much smoother than the old Hybrid Perpetual, and very free-flowering for one of this class, when I saw several rows of it at Belmont. It was staged more than once before it obtained the gold medal at Belfast, the National Rose Society's Provincial Show of 1912, and where, I suppose, the keenest competition I ever remember in the class of new seedlings was seen, for many Roses staged in magnificent form at this show were passed over, only to receive the gold medal later, notably, British Queen, Colleen and Mrs. James Lynas, to mention only three that occur to me.

speak more definitely of it. At its best it is the most beautiful white Rose that we have, and a well-grown flower will always tell in the exhibition box. At the same time there is more Tea blood in its veins, and it is a long distance away from a scented Frau Karl Druschki. The petals are shorter than that Rose, but it keeps its beautiful shape for a long time and has a great number of petals, though some of them are small. In a word, it is quite distinct, fragrant, very free-flowering and very beautiful. It has a fault—what Rose has not?—and that is in its method of growth. The laterals or side shoots are produced horizontally to the ground, and consequently the flowers are not held upright, somewhat after the style of Mrs. Herbert Stevens; in fact, I have little doubt the two are close relatives. For a Rose that was expensive last year it has been frequently shown, both in twelves and in trebles, especially by the trade. A very good basket of it was shown by the raiser at the autumn show of the National Rose Society, and it actually had the audacity to beat George Dickson in the same class. One would not expect it to do that often. It is a fine garden Rose, very tree-flowering, and I can strongly recommend it. It makes a very charming button-hole.

Southampton.

HERBERT E. MOLYNEUX.

ROSES IN CHURCHYARDS.

THE surface of the churchyard is the freehold of the incumbent, whether rector or vicar, so the grass belongs to him; he can make hay of it if he chooses to do so. In days happily gone by, sheep grazed in the churchyard to keep down the grass, and even now in some few cases the state of the churchyard is deplorable; long, rank grass, clumps of nettles and

bowed tombstones. But for the most part times have changed, opinions have changed, and with them a change has come over the churchyard. Let us see the reason. God's Acre should not only be kept trim and neat because it is the threshold of God's House, but more so because it is the resting-

place of the bodies of those "called to be saints and of the household of God"; the bodies of our dear departed ones. And because there has been, and still is, a growing appreciation of that Article of the Catholic Faith, "I believe in the Communion of Saints," the memory of the Blessed Dead extends from the altar to the churchyard. The grass is kept close cut like a lawn, and flowers are planted in every available space, especially Roses.

There are several churchyards in the neighbourhood of the writer wherein Roses grow and flourish, one of these being the beautiful churchyard of St. Peter's, South Weald. The red-tiled roof of the handsome lych-gate is covered from top to bottom with Crimson Rambler; the paved way leading to the main entrance to the church, a noted Norman arch and doorway, is flanked on either side by standard Rose trees, of which some have from time to time been replaced; but the majority, together with the rambler over the gate, are at least twenty-eight years old. Pillar Roses and standards are dotted here and there about the church, as will be seen by the illustrations, and dwarf bushes shelter themselves by the buttresses of the church walls. In addition to Roses, bulbs in spring, Geraniums and others make God's Acre beautiful.

And it has all come to pass in this wise. When, in 1895, Mr. Christopher J. H. Tower of Weald Hall was invited to become the parson's churchwarden, the churchyard was in a more or less neglected condition. Mr. Tower accepted, provided that he should be allowed a free hand in the upkeep of the churchyard, and from that day to this he has had charge of it. A man is specially employed four days a week; the sexton has no hand in it. The whole of the financial expense is borne by Mr. Tower with the help of his neighbours. Surely all who help in this labour of love must be glad to see how well the plants and flowers respond to the care bestowed, and the parishioners proud to know that their own churchyard is now one of the most beautiful in the county of Essex.

J. H. PEMBERTON.

ANOTHER VETERAN ROSE BUSH AT SOUTH WEALD. THE DIAMETER OF THIS IS ABOUT 8 FEET, AND THE BUSH HAS BEEN PLANTED OVER THIRTY YEARS.

GARDENING FOR BEGINNERS.

ROOTING CUTTINGS UNDER BELL-GLASSES.

COMPARATIVELY speaking, there are very few hardy shrubs which cannot be multiplied by means of cuttings. It is not surprising, however, considering the great variety of shrubs cultivated in our gardens, that several different methods are necessary. Quite soft cuttings made of the young shoots of some shrubs will root during July in a propagating-frame with plenty of artificial heat. During August and early September cuttings made of the half-ripened wood do admirably in a close frame, preferably with a little bottom-heat. A third and very easy means of increasing many of our most popular shrubs is the method illustrated. October is about the best time to insert cuttings under bell-glasses, as at this season the shoots made during the previous summer are fairly hard or ripe, and will make the best plants.

Position for the Bell-Glasses.—Choose a sheltered position under a fence or hedge, protected from the sun during the middle of the day, yet one where the young plants as soon as rooted obtain plenty of light. The soil should be well drained, light and sandy; if at all heavy, a raised bed of soil, kept in position with boards as shown in the illustration, may be prepared. Place in the bottom 3 inches or rather more of rubble or clinkers for drainage; then fill up with 4 inches to 5 inches of light, prepared soil consisting of two parts sandy loam, one part peat, one part leaf-mould and one part coarse sand. Make the whole firm and level the surface, spreading over it a thin layer of silver sand, which will trickle in the holes round the cuttings as they are inserted. For convenience of inspection and attention the prepared bed should not be too wide; a sufficient width to take three rows of bell-glasses is ample. The bell-glasses vary in size from a diameter at the bottom of 4 inches to a foot. The size of the cuttings must of necessity vary in length and thickness according to the nature of the shrub, whether slender or stout in growth. An average length will be from 3 inches to 6 inches, inserting about one-third of this length in the soil. Whenever possible, the cuttings should be made with a fragment of the old wood attached to the base; this is familiarly termed a "heel."

In most cases it is desirable to cut off 1 inch or 2 inches at the top of the shoot, the growth being tender or soft and liable to damp off in winter. With evergreen shrubs this is not so important, the leaves tending to keep the shoots fresh. Before dibbling in the cuttings, the bell-glass should be placed on the prepared bed and pressed in the sand to mark the outside of the patch of cuttings. This is plainly shown in the illustration. The number of cuttings inserted under a bell-glass will depend on the

CUTTINGS OF *OLEARIA HAASTII* JUST INSERTED AND READY TO BE COVERED BY THE BELL-GLASS.

size of the cuttings and the amount of ground covered by the bell-glass. Under a bell-glass 4 inches to 5 inches across it is possible to insert forty to fifty *Erica* cuttings, as these are only 1 inch to 1½ inches long. A bell-glass a foot across will cover fifty cuttings of *Tea Roses*. It is not necessary to limit each bell-glass to one kind of cutting. Choose those which are similar in size and which take about the same time to root. Label each one

CUTTINGS OF VARIOUS SHRUBS IN SPECIALLY-PREPARED SOIL AND PLACED UNDER BELL-GLASSES.

carefully, and put the date when inserted on the label for reference. To prevent the cuttings flagging, roll them in a wet cloth as soon as they are cut off the parent bush; this will be found more convenient than placing them in water. The cloches used so much in French gardening will answer the same purpose as the bell-glasses; hand-lights may also be used. As it will be desirable to afford a little protection to the cuttings during severe frosts, the bell-glasses should be conveniently placed so that they may be covered with Bracken or the old, dry tops of *Michaelmas Daisies*. The cuttings should be well watered as soon as inserted with a fine-rosed watering-pot to settle the sand round the cuttings. Further watering will probably not be necessary more than once a month till the end of January.

Cuttings of Shrubs to Insert Now.—*Olearia Haastii* (the Daisy Bush), shown in the first illustration—this is one of the best flowering shrubs for the small town and suburban garden; *Berberis stenophylla* (the Hybrid Barberry); *B. Darwinii*, a Chilean species with orange-coloured flowers; *Laurus tinus* or *Viburnum tinus*, *Veronica Traversii*, the double *Furze* or *Gorse*, the *Rosemary* (*Rosmarinus officinalis*), *Lavender*, *Cotton Lavender* (*Santolina Chamæcyparissus*), hardy *Heaths*, the several varieties of *Cypress*, *Lawson's Cypress*, *Yews*, *Tea Roses*, *Brooms*, *Box* and *Escallonias*.

HINTS ON WINTERING GREENHOUSE BULBS.

THE greenhouse bulbs that I am now particularly referring to are *Achimenes*, tuberous *Begonias* and *Gloxinias*. In many instances the bulbs and tubers are left in the pots and pans in odd places on the stages or shelves until the latter part of the year before any attempt is made to store them. Curiously enough, the haphazard way of treating them up to this point has been quite satisfactory, as they have been so gradually rested. Afterwards, however, owing to mistakes in storing, the tubers and bulbs have rotted.

It is wrong to place the bulbs under stages close to the hot-water pipes. They may be stored under staging if kept 2 feet away from the pipes, and also if a board is placed between them and the pipes; furthermore, if drip can be avoided. A corner position on the stage itself is a very good one in which to winter the plants, bulbs and tubers. Very few will be lost. Owing to lack of space the tubers are often taken out of the soil and stored close together in boxes. This plan answers if shallow boxes and sand in which to store the tubers are used. *Achimenes* should be left in their own soil until next February, when it will be advisable to take them out and repot or repan them again. SHARROCK.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Flower Garden.

Flower-Beds.—By this date all flower-beds should be filled with their occupants for making a spring show, and all surplus and small bulbs may be planted either in the borders or in the wild garden, as may be deemed desirable.

Chrysanthemums.—Many of the old border Pompon varieties are much more hardy than the newer types, and may be left out in the ground all the winter, at least in most situations, but the latter, to make quite sure of them, should be lifted and placed in a frame to ensure good stock in the spring. No heat is necessary, but just sufficient covering to keep them moderately dry, when they are less liable to injury by frost. Needless to add, they should not be lifted till the flowering period is over, and even then they ought not to be cut down too low for a time, or the stock is much weakened by bleeding.

Fuchsias.—The different varieties of hardy Fuchsias should be protected by giving them a covering of very light soil, leaf-mould or ashes over the crowns of the plants.

The Pleasure Grounds.

Acer californica aurea.—This is one of the most effective golden foliage plants in a bed that I know. Though not such a robust-growing plant as the Silver Acer, it is much more effective, especially where there are many dark green trees. It cut back fairly hard in the spring, it retains its colour (golden yellow) till quite late in the season.

Tamarix hispida æstivalis makes a fine bed, and when established throws up grand spikes or stems of flower, which remind one somewhat of Pampas Grass, except that the colour is a delicate mauve. To get the best results this plant also wants cutting hard back early in the spring, when it will flower well during July, August and September.

Berberis Darwinii and **B. stenophylla** are two plants which are hard to beat for a spring effect. Single plants in the borders are very fine, but large beds that may be seen from a distance are even better. The latter variety, with its long, arching racemes of bloom, is probably the best of the two.

Viburnum plicatum and **V. Opulus** are two very useful flowering shrubs, and can hardly be placed in a wrong position. The latter needs careful pruning (after blooming) to keep it in bounds, and both of them add a certain amount of colour to the shrubberies during the autumn when the leaves are turning colour.

Plants Under Glass.

Begonia Gloire de Lorraine and its various types that are well advanced in bloom should be placed in a somewhat drier house with a temperature of 50° to 55° at night. Keep them moving by giving weak liquid manure, and they will keep in good condition for months. Give more space to the later plants as they require it, and practically the whole of them may be allowed to flower now. They should be in real good form before Christmas.

Bouvardias developing their flower-buds must be given a nice, even temperature of about fifty-five to sixty degrees, with just a suspicion of moisture in the atmosphere. Under such treatment young plants should go on blooming throughout the winter, and provide plenty of flowers for the table and button-holes. This is a plant that has had to give way in many places to the winter-blooming Carnation, but even now it is well worth looking after.

The Kitchen Garden.

Celery.—Even the latest rows of Celery should be finished earthing by now, or the frost will injure the leaves. Make the banks very steep where the soil is heavy, so as to throw off the water as much as possible. When digging Celery for the house, be sure to burn all outside leaves and roots, so as to counteract as much as possible the depredations of the mining maggot during the coming season; also, the soil should be carefully levelled as digging proceeds, so as to leave the ground in a tidy condition.

Artichokes that have died down may be lifted, sorting over the tubers and storing those together that are of serviceable size, reserving the medium-sized ones for seed, while the small ones may be

given to the pigs. In some localities these are very late in dying down, and lifting should be delayed till frost kills the tops.

Fruits Under Glass.

Strawberries for Forcing.—If not already under cover, the early batches should be placed in frames at once, preferably with ashes between the pots, thus preventing them getting cracked by frost. Plenty of air should be given on all occasions, it being only necessary to keep the heavy rains from them. When frames are not available, the plants may be laid on their sides under a wall, placing ashes or leaves between the layers of pots to keep them in position and to prevent cracking of the pots, as advised for the frames.

Hardy Fruit.

Fruit Trees : Selection of Varieties for Planting.—Before planting any number of trees in a district where one has not had much experience, it is advisable to make enquiries as to the varieties which do best, and plant these in sufficient quantities to secure a crop, adding others more or less for trial purposes. There are, however, some varieties that are fairly good croppers in nearly all districts, and in planting Apples for cooking purposes one cannot, or should not, overlook the merits of Ecklinville, New Hawthornden, Lord Suffield, Warner's King, Beauty of Kent, Blenheim Orange, Bramley's Seedling, Lane's Prince Albert, Northern Greening and Newton Wonder, while the old variety, Tom Putt, is one of the best croppers with me, and is not at all a bad-flavoured variety for use just now, Lane's Prince Albert being perhaps the heaviest cropper year in and year out.

Dessert Apples are always in demand, and though in the early part of the season we get some good-coloured fruits, the quality and flavour in some of them are not all we desire. James Grieve is splendid, but it must not be left too long, or it will be found soft and insipid. Benoni is one of the best early Apples, and deserves to be very widely known; it comes in during September. King Harry is also good. Rival proves itself to be of good colour, flavour and keeping quality, and is not a bad cropper on cordons. Duchess' Favourite and King of the Pippins are the two most consistent croppers in this district, while Cox's Orange, Cox's Pomona, Ribston Pippin, Worcester Pearmain and Charles Ross can be relied upon to give a fair sprinkling of fruit each season.

THOMAS STEVENSON.

(Head-gardener to E. Mocatta, Esq.)

Woburn Place Gardens, Adlestone, Surrey.

FOR NORTHERN GARDENS.

The Flower Garden.

Bulb-Planting.—This work should now be finished without delay, more especially bulbous lilies, as they often decay if left out of the ground after October.

Lifting Chrysanthemum Stools.—Chrysanthemums have flowered extra well this autumn. They are, however, pretty well over now, and stools for stock should be secured. Cut the plants down to within 6 inches of the ground, lift with a digging fork and box them up, working some light, rich soil in among the roots. Give the boxes a good watering, and after the water has settled give the whole a good sprinkling with soot to ward off the attacks of slugs. Place the boxes in a cool frame or pit, and give plenty of air on all favourable occasions. Our stock here (all of which I can recommend) consists of the following varieties: All the members of the Massé family, Lady Mary Hope, Polly, Carrie, Beacon, Dainty, Lily, Mrs. A. Thomson, J. C. Grieve, Abercorn Beauty, George Wermig, Goacher's Crimson, White St. Croutts, Little Bob and Rosie.

Herbaceous Plants.—This is probably the best season of the year either for making new plantations or for making alterations among existing stock. In the case of new plantations, the beds or borders should first be trenched at least two spades deep, and a good dressing of manure should be dug in.

The Rock Garden.

Building.—One should always keep in mind that what is wanted is not a display of stones,

but a suitable environment for a particular class of plants. While all appearance of stiffness and uniformity should be avoided, yet certain guiding principles must constantly be kept in view. The first of these is to form pockets (as diverse in form as possible) that will hold a sufficiency of soil, and that will catch and hold the moisture supplied to the plant, whether by natural or artificial means. There is something radically wrong with the building of rockwork which requires sprinklers playing on it most of the summer. The bigger stones should mostly be placed in the background, but a few of these should be mixed with the smaller stones to break the monotony. Embed the stones so firmly in the ground that one can stand upon them for purposes of planting, top-dressing, weeding and admiring.

The Rose Garden.

Mulching.—Most experts now condemn the old practice of giving Roses a winter mulching with solid manure, as it keeps the roots in a cold, wet condition. A common practice now is to draw a little dry earth up to the necks of the plants, so as to run off the winter rains, and then to give a dressing of well-rotted manure in spring. My own practice, which produces excellent results, is to mulch with half-decayed leaves. The rougher part of these is removed in spring, when the beds generally get a dressing of bone-meal, soot and ground lime previous to their being forked over.

Plants Under Glass.

Late Bulbs.—If any bulbs remain unpotted, they should be potted up at once and placed in the plunge. Remove earlier batches from the plunging material after they have been in it about six weeks, and place them in a cool frame or pit.

Lily of the Valley.—This is always acceptable, especially in the dull days of winter. Strong, retarded crowns give the best results. Pot them up rather thickly in 5-inch pots, the crowns just showing above the ground. Keep them in a cool pit, and bring them into the forcing-house in batches as required. Plunge the pots in a brisk bottom-heat, and keep each pot covered with an inverted pot of the same size till the plants have made about two inches of growth. Never allow them to lack for water at the root, and spray with tepid water twice daily. They should be fit for use in from twenty to thirty days if treated thus.

Fruits Under Glass.

Late Grapes.—Few things tax the Grape-grower's skill more than the maintaining of his late Grapes in really good condition throughout the dull, damp autumn days. To maintain a dry, buoyant atmosphere at a comparatively low temperature is the crux of the matter, and nothing but close observation and attention will secure the desired end; but bunches laid on the table with symmetry of bunch and bloom of berry unimpaired will repay all the trouble.

The Hardy Fruit Garden.

Planting Fruit Trees.—It is now universally admitted that, except in the case of a very few highly-favoured localities, the cultivator's constant aim should be to keep the roots of his trees near the surface, where light, air and heat will have a beneficial influence upon them. It is when the roots are allowed to penetrate into the cold, wet, or, it may be, actually poisonous subsoil that canker and other diseases attack the trees. Most good cultivators now plant the trees on the original surface and cover the roots with about six inches of fresh loam, mulching the surface with half-decayed farmyard manure immediately after planting. If shallow pits are dug out for the trees, they should be made quite flat, and some fresh loam be worked in among the roots. Tread the ground firm and mulch as indicated. Stake and tie standards, and nail wall trees promptly. A piece of coarse cloth should be placed round the stem of the tree to prevent the ligature from damaging the bark through friction.

The Vegetable Garden.

Rhubarb.—Where an early supply of Rhubarb is wanted, a few crowns should be placed in heat now.

Manuring.—Advantage should be taken of dry weather or frosty mornings to wheel manure on to vacant quarters which are to be dug, and digging and trenching should be pushed forward, especially in districts where the winters are usually severe and long.

CHARLES COMFORT.

THE KITCHEN GARDEN.

SOME UNCOMMON VEGETABLES.

HINTS ON COOKING AND SERVING

THE conservatism of the average Briton in matters of food is notorious, and my object in writing these few notes is to stir him up to the fact that there are certain vegetables of which he might make more use, and, incidentally, that there are a good many that might be more satisfactorily cooked and served than they are. I am not a vegetarian, but I possess a keen appreciation of the properties of good vegetables, both from the points of view of palate and stomach, and I am one of those who consider the vegetable course that one gets in the best hotels and restaurants a blessed institution.

An often overlooked point, too, is that a good number of vegetables are by no means ill eating when cold, some of them making an excellent salad served with cold meat. In this category come Peas, Broad Beans (young), Globe Artichokes and young early Carrots, the last delicious. There is no reason why any of those I have named should be wasted after having been served at a hot meal. In a recent conversation with a large hotel-keeper, he was telling me he could not get his guests to eat Globe Artichokes, and he was not surprised, as, in his opinion, there was hardly any food in them. Now, Globe Artichokes are a specially favourite vegetable of mine, and those who grow them well will know that there is plenty to "bite at" in them if devoured in a sensible way, and for flavour they are very hard to beat.

A vegetable that I seldom come across, save at my own table, is the little green-seeded French Haricot, sold by Sutton and Sons under the name of Green Gem. These Haricots, when shelled out while young and cooked with a small Onion, make a most appetising dish, and everyone who tastes them here seems to like them. These also should come under my little list of things that are good when cold. Celery, or Turnip-rooted Celery, is seldom seen, but here we find it good both hot and cold; the flavour to me is reminiscent of both Celery and Parsnip, and, as it is so easily cultivated and does not require the labour and space of ordinary Celery, I do not understand why it is not more grown and eaten.

The Cooking and Serving of a number of our vegetables in this country leave much to be desired. For instance, when I go into the garden and cut a dainty, snow white little Cauliflower, I strongly object to having it served up with a smothering dose of sticky and insipid melted butter; and I should like to know why the average cook, as soon as she (or he) has cooked a few nice young Beet-roots, at once slices them and plunges them into vinegar, making a pickle of what ought to be a dainty dish with a refreshing and appetising flavour quite its own. I prefer to slice my Beetroot myself, and eat it without vinegar or any such futile adjunct; but, of course, it must be quite fresh, and is of no use the second day, while the vinegar-preserved article may be kept going for a week or more—but in any case, none of it for me.

Then there is the Custard Marrow, most delicately flavoured of its race; it should be cut young and small, and cooked whole with the rind on, the latter being removed after cooking. I wonder if anyone has tried it thus, dressed with a little cream. It is a dish fit for an epicure, and should be tried as a vegetable course, alone. Harking back to

Beetroot, there is a dish known on the other side of the Atlantic as "Beets"; this is simply the small round or Turnip-rooted variety cooked young, in quantity, and served hot, and in this form it is by no means to be despised. A pretty good test of a cook is the way a Cabbage is cooked and served. Notwithstanding all oral and written instruction, I regret to say that a large proportion of cooks will send a Cabbage to table a shapeless mass of hotch-potch; your well-regulated cook will carefully tie it before it goes into the saucepan, and, after it is done just to a turn, will serve it up whole and undismembered, a delight both to the eye and the palate.

Rye

F. HERBERT CHAPMAN.

THE CULTURE OF POTATOES

At the recent Fruit Congress held at Kendal, Mr. G. P. Berry lectured on "The Cultivation of Potatoes." Mr. Berry said that the want of lime in garden and other soils was disastrous to Potato-growing. The Potato was a plant which loved sun and air. Nothing enabled the gardener and allotment-holder to resist attacks of disease in Potatoes so much as wide planting. He recommended growers to have the quality of their soil chemically tested, the manuring, loam, clay applied to some soils, and wood-ash to others, were desirable. As manure for early Potatoes recommended by Professor Wallace, Mr. Berry gave the following: Eighteen to twenty tons of ordinary farmyard manure and chemical materials at the following rate—60 lb. of sulphate of ammonia, 60 lb. of superphosphate (25 per cent. soluble), 20 lb. of potash salts (35 per cent. solution), 10 lb. of guano containing 6 per cent. ammonia and 40 per cent. of phosphate. This should be applied at the rate of 120 lb. per acre. In planting, care should be exercised. Very small Potatoes should not be used as seed, and a Potato had a tendency to reproduce the characteristics of its parent plant. Having selected the Potato, whether first early or second early, it was found advantageous to box the seed Potatoes. It appeared that certain lads on the Potato tiler were in more direct contact with the stored-up material within than others. Better results were got when a Potato produced two or three good strong stems than when it produced seven or eight weaker stems. To facilitate the decay of each tuber, a small piece should be cut off the base end of the tuber. In gardens and in allotments it paid better in almost every instance to plant Potatoes whole. During the season the ground should be kept as loose and porous as possible; and, in market-gardening especially, the heavier the soil the higher should the stiches be made. As to storing Potatoes, it was best done in sheds and boxes, in which the early varieties did not run the risk of heating. Mr. Seaton of Leeds, who was asked to speak, said that from the agriculturist's point of view the question of bulk was made the great consideration; the farmer did not concern himself much with quality. In Yorkshire they did not grow Potatoes of the same eating quality as those grown on the Dunbar soils. He knew of a tavern in London where he could always get good Potatoes at the table—Potatoes with a peculiar close, starchy look outside; a Potato which was firm and dry, with a flavour which would satisfy an epicure. He could not ascertain whether that excellence lay in the cooking or in the variety; it might be in soil conditions or in climatic conditions. Many important points in connection with Potatoes were awaiting solution. The question of liming, for example,

was one of many, and, as Mr. Berry had said, was being revolutionised. He would, however, warn his hearers that lime seemed to have a tendency to produce scab. As to the use of muriate of potash, it had been condemned as producing waxy Potatoes; but he suggested that that was when a low-grade muriate of potash was used, because it contained a large proportion of common salt.

TRIALS AT WISLEY IN 1914-15.

THE Royal Horticultural Society have arranged for the following trials to be held at Wisley. Everything sent for trial must be named, and the name and address of the sender attached, together with the name of the raiser and introducer as far as known.

Melons.—Ten seeds of each variety to be sent in February.

Herbaceous Phloxes.—Three plants of each to be sent in February.

Early-Flowering Outdoor Chrysanthemums.—Three plants of each to be sent in March.

Pentstemons.—Three plants of each to be sent in March.

Perennial Sunflowers including Heleniums and Rudbeckias.—Three plants of each to be sent in February.

Asters French, German, or China.—Seed to be sent in February.

Broccoli.—One packet of seed of each to be sent in February.

French Beans Outdoor.—One pint of seed of each to be sent in March.

Tulips.—In view of the confusion existing in the nomenclature of Tulips, the Council of the Royal Horticultural Society have been requested to draw up a list of synonyms, and have consented to do so with the co-operation of the Dutch growers. It is accordingly proposed to plant this autumn at Wisley (where Tulips do so well) as representative a collection of all classes and descriptions of Tulips as can be got together. Growers in Holland are asked to send over their bulbs to be grown side by side with those from English growers. Five bulbs of each variety should be sent during this October. When they are in bloom, a joint committee of Dutch and English Tulip specialists will be invited to meet at Wisley to determine the correct nomenclature. A synonymic list will then be prepared and issued. It is important that all bulbs sent should bear the name under which they are known or sent out by the sender, and also an indication of their type, as early, late, Darwin, Parrot, bizarres, hybridisms, roses, &c. If sent by post, they should be addressed to The Superintendent, Royal Horticultural Society's Gardens, Wisley, Ripley, Surrey; if sent by rail, to The Superintendent, Royal Horticultural Society's Gardens, Wisley, Horsley Station (London and South Western Railway), with advice by post to the Superintendent.

Horticultural Sundries.—The Council will continue their trial of horticultural sundries in 1914 under the scheme introduced in October, 1912. The system then adopted has proved admirable after twelve months' practical test, and sundriesmen are again invited to send their specialities (not more than three articles in any one year). Full particulars, with entry form, can be obtained from the Secretary, Royal Horticultural Society, Vincent Square, S.W., upon receipt of a stamped addressed envelope.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS. *The Editor undertakes to make THE GARDEN helpful to all readers who desire assistance, on matters which the branch of gardening may be, and with that object will make a special feature in the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants in botanical questions should be clearly and accurately named, and flowering shoots where possible should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.*

FLOWER GARDEN.

OLD-FASHIONED ANNUALS FOR AN EAST BORDER (Suffolker). The following kinds of annuals will thrive well in the east border, namely, *Mignonette*, Stocks, Asters, *Phlox Drummondii*, *Marguerite*, *Andryant*, Lupines, *Larkspurs*, *Clarkias*, *Linum tuberosum*, *Campanula*, *Virgatum Stock* and Sweet Peas. Seeds of the Stocks and Asters must be sown in a frame and the resultant plants put out in May. Seeds of the other kinds should be sown in the open borders early in May. The *Virgatum Stock* makes a nice edging, and the *Mignonette* looks well if grown in clumps behind it.

FLOWERS FOR AN ISLAND GARDEN (M. L. W.).—The following kinds of climbing Roses are likely to thrive on the island you describe: *Dorothy Perkins*, *Crimson Rambler*, *Auguste Barbier* and *Rosa avicinis flore pleno*. You might also secure a good effect by planting a group of the Japanese Rose, *Rosa rugosa*. Both golden and red stemmed Willows will give satisfactory results, and will probably be more successful than the red-stemmed Dogwood. A few other shrubs for decorative effect are *double-flowered Gorse*, common *Broom*, *Berberis sonophylla* and *Hypericum calycinum*, the latter for the banks or margins. Another showy shrub of rambling habit is the *double-flowered Blackberry*, *Rubus nitidifolius flore pleno*. The common *double Dahlia* will be suitable for planting as you describe, while *Empereur* will also grow on heavy soil.

IRIS KÄMPFERI (L. B.). The best of all times in the year for transplanting this Iris is just prior to the commencement of its new growth, say, mid-March to mid-April. As the new quarters are not yet ready, leave the plants where they are for the winter, unless the old position is flooded with water, and divide and replant in spring. It is a mistake to transplant big clumps of this or any Iris intact, and not a few failures result therefrom. Hence, in conjunction with transplanting, there should always be a division of the rootstock. Moisture within reach of the root-fibres of sward-saturation in summer-time or during growth is quite good for the plants, while those plants that are wholly or partially submerged in winter are calculated sooner or later to perish as the result. Conversely, a condition of much dryness in winter-time would appear abhorrent to the plants. In some instances it might prove fatal; in all, decidedly weakening in effect.

HERBACEOUS BORDER (J. H. M.).—It would have greatly assisted matters had you stated the nature of the soil. Generally speaking, however, *Hop Manure* is regarded as a good substitute for organic manures, though in your case it might require a liberal application. You should in conjunction with it employ a good dressing of lime, say, two bushels per rod of ground, to be forked in as the trenching of the border proceeds. The burnt ash should also be well incorporated with the soil. Assuming that the *Desmodium* is a comparatively youthful plant, it may be transplanted as soon as the flowering is over, and in your district would soon re-establish itself. Spring, with returning growth, would, however, be a better time for older examples, and particularly so where a clay soil exists. March, or with the first signs of returning growth, would be the best time to divide the *Genium*, for which a bed, 2 feet or 3 feet in depth, of rich loamy soil should be prepared. In replanting, your best guide will be the buried depth of the old plant, though it is not advisable to place the crown much below the surface of the soil.

PERENNIAL BORDER (Walford).—Your idea of "trenching as you go," and, we presume, of planting, too, is wrong, and will not lead to good results, more particularly since you now have a desire to arrange the border for "effect." That being so, we should advise that you clear the border of its present occupants—a three years' tenon of the soil is not a bad one—level them in many convenient spots, and then thoroughly trench and manure the ground in readiness for planting later on. Then, if you prepare a group, you would in all probability obtain the effect which you desire. In this connection it would help you considerably if you obtained "The Hardy Flower Book," by E. H. Jenkins, and study the plans therein given, together with the chapters on planting for effect. In such case the planting might be deferred till March, the border having in the meantime been trenched, rested, and

also refreshed and aerated by frost, sun and rain. By these means the seedlings might be protected in pots or frames till ready for use. It is highly probable, too, that the *Chrysanthemums* in flower and *Pentstemon* seedlings if put out in October would suffer from frost, and, of the former, in any case you should hold plants in reserve in a frame, since they are not only unreliable in severe winters, but young plants invariably give the better results. The *Glabell* and *Hyacinthus candicans* should be lifted at once, gradually dried out, and stored in a frost-proof place till March, when they may be replanted. The bulbs of these plants may continue to give good results for years if treated annually as advised. You need have no misgivings about the manure. Shuk a shallow pit in some out-of-the-way corner and place it therein. By covering it with the excavated soil—a most efficient deodoriser in such cases—all objectionable smell would be prevented.

TREES AND SHRUBS.

PYRACANTHA LALANDI NOT FRUITING (E. J. P.).—It is impossible to give a reason for your plant of *Pyracantha Lalandi* failing to fruit. If it is growing freely, there is no reason to give it manure, but if the shoots appear to be weak and the foliage thin and pale in colour, manure may do good. Do not overprime it for a time, and perhaps, as the wood gets older, fruit will be borne. There is a possibility that your plant was raised from seed and the fruiting plants of which you speak from layers, which would account for the earlier flowering and fruiting of the smaller plants.

LOPPING ELMS (M. P. S.).—There is no test by which you may ascertain when old Elm trees require lopping; but if you observe decayed places about the branches, you may safely regard them as needing attention. Branches which are quite sound, however, have an unaccountable way of breaking off not only during wind, but on quite calm days, and when old Elms occur near houses, or in places where people are in the habit of congregating, it is much the safest plan to lighten all the heavy branches. Trees which have dead tops may often be rejuvenated by removing the dead portions to places where the wood is quite sound, new shoots succeeding the operation.

PRUNING CLEMATIS (J. H. J.). The large-flowered *Clematis* is *Ville de Lyon*, and the small-flowered one is *Vitellia*. Both kinds may be cut back to within two or three buds of the base of the previous year's shoots in February each year. If cut back less severely, the plants are apt to become bare at the bottom, owing to the upper buds breaking away and the lower ones remaining dormant. Should you wish to extend the plants, however, you may leave eight or nine of the lower buds and bend the plants into a horizontal position, which will induce more buds to break into growth. Should such a course be adopted, care must be taken to prevent the shoots becoming entangled.

HEATH FOR NAME AND TREATMENT (Constant Reader). The specimen sent for name is a richly-coloured variety of the common Ling (*Calluna vulgaris rubra*). We are afraid little can be done to improve the old plant. A much better plan will be to propagate a stock of young plants from the old one by inserting cuttings now. Make the cuttings three-quarters of an inch to 1 inch long, and insert fairly thickly, in pots of light, sandy soil made up of two parts peat and one part sand. Place in a close frame, in a handlight or under a bell-glass, till rooted. They should make nice plants, which will flower the second year from cuttings. The common Laurel may be clipped at any time from April to August.

TREES TO MAKE A QUICK-GROWING SHELTER (Scrib.).—You cannot do better than plant *Poplars* in the position you describe. The one grown in the nurseries as the *Black Italian Poplar* is the most suitable one for the purpose. These can be procured up to 15 feet in height, but possibly those 8 feet to 10 feet high will be more suitable for your windswept land. Purchase plants with strong, sturdy trunks which are capable of supporting their own weight, rather than those with slender trunks, which will continually need attention. It is possible that quite strong trees will require staking until they are well established, and it will be advisable when planting to allow the heads to fall slightly towards the wind. Early planting will be advantageous.

THE GREENHOUSE.

VINES IN GREENHOUSE (S. M. L.).—Keep the greenhouse as cool and airy as you can during the winter consistent with the welfare of the *Ceraniums*. Let the Vines break naturally into growth in the spring without any forcing and applying extra heat. Do not overtop the Vines with foliage during the summer. The branches of the Vines on which the bunches of Grapes appear (and which are termed spurs) should not be nearer together than 15 inches (we mean 15 inches between the spurs on either side). As soon as each spur in spring has made a growth of three or four small leaves beyond the leaf opposite to which the bunch is situated, let the spur be stopped by pinching it off with the finger and thumb immediately above the third small leaf. Subsequent young growth to which the bunch is on subsequent young growth will issue from each spur in the course of the summer. Let each of these, no matter where situated, be pinched back at the top of the third young leaf as soon as it is formed. This effectively prevents overcrowding of the foliage of the Vines during the summer, giving the spurs a chance to develop and ripen their growth for the production of a good crop the following year. Do not give any front air to your Vines before the middle of April. The temperature up till then may be regulated by top or back ventilation. As the heat of the summer advances,

more air must be given to the front and back. With regard to the border, it must always be kept free from weeds. Fork into the border now, 4 inches deep, boned and lime at the rate of one quart of each to the square yard. Cover over your border at the end of this month with littersy straw to the depth of 4 inches. Take this covering off at the end of April, give the border a good soaking of manure-water at the same time, and cover over a few days afterwards with a layer, 4 inches deep, of well-decomposed farmyard or stable manure as a mulch for the summer. Water as you have done before. Good results should follow this treatment.

ROSE GARDEN.

ROSES DESTROYED BY CATERPILLARS (A. Subscribes).—We think if you were to well spray the Roses with *Carlton Arsenate of Lead Paste* you would check the trouble. It is obtainable from Messrs. W. Voss and Co., Millwall, London, E. Dip the roots in the solution, and, when planted, well spray the branches and continue the spraying throughout the summer at intervals of ten or twelve days.

ROSES FOR FLORISTS' WORK (G. S.).—Mrs. Herbert Stevens would be a valuable white, and you should also plant some *Frau Karl Druschki*, also *Yvonne Rabier* for sprays. A dozen good kinds to plant in quantity for your business would be *Lady Hillington*, *Lady Pirrie*, *Mme. Abel Chateaux*, *Mrs. Alfred Tate*, *Duchess of Wellington*, *General MacArthur*, *Lady Roberts*, *Mme. Ravary*, *Sunburst*, *Florence H. Veitch*, *Chateau de Clos Vougeot* and *Lady Ashtown*. Have them all on the seedling Briar stock.

BUDDING BRIARS IN TUBS (Reader).—While we do not say the operation would be impossible, we strongly advise you not to attempt it. The standard Briar requires a deal of looking after when potted up or planted in tubs. It would be much better for you to plant them in the garden in rows 3 feet apart and about a foot apart in the rows. Fifteen good varieties for exhibition would be *Mrs. John Laing*, *Frau Karl Druschki*, *Dean Hole*, *Lyon Rose*, *Caroline Testout*, *J. B. Clark*, *Hugh Dickson*, *Margaret*, *Lady Ashtown*, *Mme. Melanie Souper*, *Mrs. George Shawyer*, *Mrs. Foley Hobbs*, *Suzanne M. Rodocanachi*, *Mrs. W. J. Grant* and *Mayflower*. Some of the kinds you name is really good as an exhibition flower.

ROSES FOR BEDDING IN A SEMI-SHADY POSITION (J. A. B.).—We are very pleased to help you in making a selection. To have Roses in bloom in August and September they must be varieties that also bloom in June and July; but as you are not in residence during these latter months, you could instruct your gardener to remove the earlier buds, as by doing so you would considerably help the second crop to bloom. Good varieties of the colours you name and avoiding those you have would be *Pink*, *Mme. Leon Pain*, *Gustav Grunerwald*, and *Lady Ashtown*, *Joels*, *Lady Battersay*, *General MacArthur*, *Leontine Chantre*, *White air*, *Blush*, *Anastine Gumbesson*, *La Tosca* and *Molly Sherman Crawford*, *Yellows*, *Mme. Ravary*, *Marie van Houfte* and *Mrs. Aaron Ward*.

ROSES WITH SUBSTANTIAL BLOOMS FOR EXHIBITION (Pablo).—We quite see your difficulty, and think that the list given below will meet your requirements. Hybrid *Perpetuals*, *Alfred Colomb*, *Charles Lefevre*, *Comte de Rambaud*, *Dr. Andry*, *Geoffrey Henslow*, *Hugh Dickson*, *Louis van Houfte*, *Mrs. John Laing* and *Suzanne M. Rodocanachi*. Hybrid *Teas*, *Alice Lemon*, *Colonel Leclerc*, *Comtesse of Caledon*, *Comtesse of Shaftesbury*, *Dean Hole*, *Dr. O'Donnell Browne*, *Duchess of Normandy*, *Duchess of Westminster*, *Earl of Warwick*, *Entente Cordiale*, *Feruchurst*, *Florence Penbenton*, *Frau Ober*, *Pique*, *E. R. Patzer*, *George C. Wand*, *Geoffrey Henslow*, *George Dickson*, *J. B. Clark*, *Jonkheer J. L. Mook*, *Lady Barham*, *Mabel Drew*, *Mme. Jules Bouche*, *Margaret*, *Mayflower*, *Mrs. C. West*, *Mrs. George Shawyer*, *Mrs. Wallace H. Rowe*, *Oberhofgartner Terks*, *Papa Lambert*, *Queen of Spain*, *St. Helena* and *Sunburst*.

MISCELLANEOUS.

NAMES OF PLANTS.—Bourville. *Rose Eugene Furst*, *W. C. Conny Antrim*, *Layestertia formosa*, *C. H. Wantage*; *Phytolacca capensis*, or *Cape Figwort*; *A. R. Jersey*; *Sollya heterophylla*, *Erica arborea*, *Elaeagnus orientalis*, *Calluna australis* (Christ's Thorn); *J. A. B. Swindon*; *Lilium speciosum*.—*Forfar*.—Cannot name from leaves only. *Ignamurus*.—*Swaifsona galeifolia*, should not be cut down, but allowed to grow. It is an An-trahan plant and has red flowers.—*Mrs. B. Salisbury*.—1, *Aster cordifolius*; 2, *A. multiflorus*; 3, *A. Noxe-Anthe* variety; 4, *A. Amelias* variety. **NAMES OF FRUIT.** *Manx K*.—*V. Bismarck*; *B. Northern Greening*; *G. H. Wantage*.—Apples too poor to name. *Pea*, *Marie Guise*.—*W. B.*—*Rainbow France*.—*D. T. Woburn*.—1, *Stoke Pippin*; 2, *Lady Henniker*; 3, *W. B. Woburn*; 4, *Blenheim Orange*; 5, *Sandringham*; 6, *Tramley's Seedling*; 7, *Royal Nonsuch*; 8, *Hacon's* (uncomparable); *Mrs. C. B. P. Dorset*.—1, decayed, probably *Lord Suffield*; 4, *Norfolk Beefing*; 6, *Manx's Codlin*; 7, decayed; 9, *Victoria*; 10, *Lamb Abbey Pearmain*; 11, *Wellington*; 12, *John Apple*; 13, *Lord Suffield*; 17, *Count Pendu Plat*; 19, *Stubbard*.—*W. M. R.*—1, *Cox's Pomona*; 2, *Warner's King*; 3, *Striped Beefing*; 4, *Brandley's Seedling*; 5, *Lord Derby*; 6, *Tower of Glanins*; 7, *Warner's King*; 8, *Peasgood's Nonsuch*; 9, *Flanders Pippin*; 10, *Fearn's Pippin*; 11, *Blenheim Orange*; 12, *John Apple*; 13, *Old Hawthornden*.—*E. G. Chantre*.—1, *Christmas Pearmain*; 2, *Hoary Morning*; 3, *Newton Wonder*; 4, *Roundway Magnum Bonum*; 5, *Sugarloaf*; 6, *Schoolmaster*.

EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

NOTES OF THE WEEK.

Shrubs with Good Autumn Foliage.—Among the many plants that give us such beautiful tints with their foliage, several species of the *Rhus* family should be noted. At the present time such as *Rhus typhina*, *R. Cotinus* and *R. cotinoides* are among the most gorgeously-coloured foliage in the gardens, and if backed with golden varieties of *Populus*, such as a bed we have in mind, the colouring is still more beautiful.

An Attractive Rock Plant.—Of the several New Zealand Burrs that we now have, *Acma microphylla*, the Small-leaved Burr, is one of the best for the rock garden with its crimson, globular heads of spine-formed calyces, which are a very conspicuous and ornamental feature of the plant at this time of the year. These look like so many crimson stars, 2 inches or 3 inches high, upon a cushion of small, green, pinnate leaves. It is a worthy plant for all rock gardens, as it will do in almost any soil or situation.

A Late Sunflower.—Though not so tree-flowering and showy as some of the September-flowering perennial Sunflowers, *Helianthus doronicoides* must be considered quite as valuable, for the blooms are at their best in mid-October. Growing about eight feet in height, the flowers are rich yellow and about two inches across. Such late-flowering plants are very useful to brighten up the shrubby borders, and also provide useful material to cut for indoor decoration. *H. doronicoides* is a North American species.

Two Good Autumn Roses.—Two of the best Roses, apart from the Dwarf Polyantha varieties, in our garden on Monday last, the 27th ult., were Mrs. Arthur Munt and General Macarthur. Both were in full flower, and the blooms were almost as full and fresh as those we had in July. Mrs. Arthur Munt, owing to the erect flowers being borne on long, stout stems, is ideal for cutting, and nearly every bloom is of exquisite shape. The colour is ivory white, with a very faint blush showing through the petals. General Macarthur we look upon as one of the best red garden Roses, and it is deliciously fragrant.

A Beautiful but Old Michaelmas Daisy.—In these days, when we have so many beautiful varieties of Michaelmas Daisies, we are apt to overlook some of the old but beautiful species, of which *Aster Tradescantii* is one of the best. It is said to be the first of the many North American species cultivated in Europe, being introduced about the year 1633 by John Tradescant, who was gardener to Charles I. In a border among many of the varieties of recent introduction, *A. Tradescantii*, with its long, elegant sprays of pure white flowers, which are borne in great profusion, is as conspicuous as any of them. This makes us think that the old kinds of flowers are not always deserving of the neglect they get.

A Late-Flowering Wall Shrub.—At this time of the year the number of shrubs flowering out of doors, either in the open or against a wall are somewhat limited, so where it is possible a place against a warm south wall should be found for *Abutilon megapotanicum*, sometimes known as *A. vexillarium*. Although it is not hardy, it succeeds perfectly well against a warm wall, and will give a profusion of blooms—the sepals of which are of a rich dark red, the petals pale yellow—from early summer till the frost comes.

A Hint for Planters.—Last May, when the crimson and pink Thorns were flowering, we saw several instances where these charming trees were in particularly bad positions; hence a word of warning seems called for now that the planting season is here. The trees in question were placed so that the dwelling-house or glaring red bricks formed a background, and anything more incongruous it would be difficult to imagine, the different shades of red clashing horribly. *Crataegus Pyracantha*, with its orange-red berries, looks almost as bad at this season when nailed tightly to a red brick wall. The moral is obvious.

An October-flowering Plum.—The present spell of mild weather is proving very favourable to hardy trees and plants which flower in late autumn. Among these, the uncommon *Prunus inoukeltana* is very prominent. It is flowering well this year. The semi-double white blossoms are about three-quarters of an inch in diameter and fragrant. Flowering naturally at this season, *Prunus inoukeltana* should prove a useful shrub to grow in pots for indoor decoration, as at this season we may any day have a frost and spoil the flowers.

Autumn-Flowering Sage for the Greenhouse.—*Salvia involuerata Bethellii* is a plant that is not grown so much now as it was at one time. This may be due to the fact that there are so many other beautiful plants for decorating the conservatory during the autumn, although that is hardly a good enough excuse for leaving this attractive plant out. It is a handsome variety, with whorled spikes of bright rosy carmine flowers borne at the end of the branches. As it is easily raised and requires little attention, it should be used for greenhouse decoration in the autumn.

Late-Flowering Saxifrages.—Although the majority of Rockfoils bloom in spring and summer, there are one or two that are valuable for their late-flowering character. One of the best of these is *Saxifraga Fortunei*, a beautiful Chinese species with erect panicles of white flowers standing well above the leaves, which are reniforme, cordate and of a glossy, dark green colour. Another species very similar to *S. Fortunei*, flowering at the same time, is *S. cortusoides*, a plant of more recent introduction, with less hairy stem, and the petals are entire. Both are quite hardy and succeed best in a partially-shaded position in gritty, rich, well-drained soil, or are excellent for growing in pots for a cool greenhouse.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

The Apennine Windflower.—This charming Windflower, *Anemone apennina*, is quite at home in a shady corner of the rock garden at Lilford Hall, Barnwell, Oundle, where it gets little sun. It is planted in loam, leaf-soil and grit, with plenty of broken stones mixed with the soil. Six plants were the beginning of the group; but now, by spreading and seeding, they have formed a patch 6 feet square, with flowers varying in colour from deep blue to almost white. We give them a surface-dressing each autumn of loam, leaf-soil and grit, and the illustration shows the result.—E. WILSON.

Failure of Pears.—Referring to the Rev. C. E. Jones' note on page 523, I am of his opinion that the cause was the long spell of cold nights at the critical period in spring. I am further North, but well protected on the north-east and south-west

Rose Aglaia.—In your admirable Rose Number of October 11, reference was made to the climbing Rose Aglaia. With me, in an old garden possessing a very light but fairly deep soil, it has succeeded beyond expectation; indeed, I cannot say too much for it. The beautiful glossy, dark green foliage is always proof against mildew, and the green fly and the maggot prefer to go elsewhere. It is most generous in blooms, producing the exquisite yellow buds in great profusion during the entire season. As a covering for, say, a summer-house, I can conceive nothing better, as the branches want to fall all round like a Weeping Willow. Of course, the pruning-knife was not made for Aglaia. May I take this opportunity to say how much indebted I feel for the many helpful hints which have come to me from THE GARDEN. I grow, in a small way, chiefly Hybrid Perpetuals, which flourish like weeds and bloom magnificently; but the Hybrid Teas (all dwarf), for some reason or other best

of the deep shades into practical politics. Hence, so defined, *V. venosa* is not a heliotrope; nor is it a violet or purple pure and simple. Under any light it is not that balanced shade which could be said to be neither reddish nor bluish. The seasaw is down on the red side always. Summing up, my answer is that it is a rich reddish purple in a mass.—JOSEPH JACOB.

Lime-Hating Campanulas.—IN THE GARDEN of October 18 I observe that Mr. Arnott, in his interesting article on Campanulas, describes *C. pulla* as a "lime-hater." This is contrary to my experience of the plant; but I have so often seen it so described, and by such eminent authorities, that it would be interesting to learn how the legend originated. Mr. Robinson advises its cultivation in peat and sand; so also does Mr. Heath of Cheltenham. Both of these instructions were published some years ago. Mr. Farrer also, a few years later, in "My Rock Garden," stated that *C. pulla* "positively dislikes lime"; but

I presume that he has since learnt the contrary from experience, as in "The Rock Garden" (a later work) he states that it grows "amongst limestone blocks in Nature." The most recent work I have—Harold Thompson's "Alpine Plants of Europe"—also states that this Campanula comes from the calcareous Alps. If Mr. Farrer and Mr. Thompson have correctly given its habitat in Nature, one wonders how Mr. Robinson, Mr. Farrer (in his earlier work) and Mr. Arnott came to describe it as a "lime-hater." Were they restating a tradition, or was the description the outcome of their experience? When I first obtained the Campanula I planted it in accordance with the directions of the authorities—in a pocket containing sandy peat. There it remained comfortably for two seasons without displaying much enthusiasm, but in its third season it suddenly appeared in the adjoining space on the rockwork—a large tract composed of loam and limestone chips, and limestone chips in plenty on the surface and devoted to alpine Primulas. Here *C. pulla* ran amok, and before the summer was over I had, in desperation, to remove all the Primulas before they were choked to death and leave *C. pulla* in possession. It has availed itself

ANEMONE APENNINA FLOWERING FREELY IN A READER'S GARDEN.

My record is: Doyenné du Comice, fourteen trees, three on wall, six Pears; Williams', five trees, half a bushel; Conference, six trees, two on wall, half a dozen; Pimaston Duchess, five trees, six Pears; Gansel's Bergamot, large tree, one peck; Louise Bonne of Jersey, four trees, one dozen; Chaumontel, heavy crop; one Bergamot Espereu, also heavy crop; Durondeau, two trees, four Pears; Bergamot, never fails, one tree, one bushel; Catillac, one tree, ten Pears; Marguerite Marillat, three trees, none; Uvedale's St. Germain, one large tree, one dozen; Beurré d'Amans, three trees, none; and about ten other varieties, none; thirty varieties, Plums Pond's Seedling and Orleans, fair crops; Victoria and Prince of Wales, a few; others none. Apples, 95 per cent.; fifty varieties heavy crops, notably Blenheim Orange, Wellington, Newton Wonder and Bramley's Seedling.—HUGH JONES, Tudor House, Monken Hadley, New Barnet, Herts.

known to themselves, are sulky and make a poor show.—J. W. COOPER, Alberta Lodge, Dalkey, County Dublin.

Verbena venosa.—I had not grown this plant until this summer, so was particularly interested in Mr. Brotherston's note on page 523. As I write I have it in a big bowl in the hall, and it is glorious, and certainly most uncommon in colouring. Mr. Brotherston asks a "poser" when he enquires about its colour. To begin with, what is violet? Interrogate five different people and I expect you would get five different replies. To me purple and violet are something like a Daffodil and a Narcissus. Every Daffodil is a Narcissus, but every Narcissus is not a Daffodil. Every violet is a purple, but every purple is not a violet. After this Delphic definition, I ask myself, what is heliotrope? I reply, the shade of the old Cherry-pie that used to grow in my father's greenhouse long before the advent

of the permission, and now occupies not only this tract, but is also endeavouring to spread from it in every direction through the limestone, and unnoticed bits evidently accompanied the Primulas to their new home, as I see the Campanula appearing there already. So far the only Campanula I have found to dislike my limestone soil is *C. excisa*, but as this never reappears with me, no matter where it may be planted, I have not been able to ascertain its "likes." Even *C. Allioni*—since I followed Mr. Farrer's prescription and planted it in moraine—lives and flowers in limestone, but it seems slow to increase. Returning, however, to *C. pulla*, there is not the slightest doubt that here, at all events, it rejoices in lime, and I should be much interested to learn whether its failure—for it is not everywhere an easy plant—can anywhere be traced to the presence of lime in the soil.—MURRAY HORNIBROOK, Knapton, Queen's County, Ireland.

Autumn-Fruiting Raspberries.—I am sending two sprays of Raspberries for your inspection. I thought perhaps it might interest readers to know that I have been gathering Raspberries all through September and October, and have a good lot now. You will see by the enclosed that the fruits are large and well worth growing, and I have plenty of them to gather every day.—H. CURTIS, *The Gardens, Harptree Court, East Harptree, near Bristol.* [The fruiting sprays sent by our correspondent were very good.—ED.]

Solidago Golden Sheaf.—Being attracted by this variety of Golden Rod as exhibited at the Royal Caledonian Society's Show in September, 1911, I bought a root of it, which was planted in the spring of last year. It failed to open its flowers last autumn, but I attributed this to the result of the cold, sunless season and the late planting. This year I looked for its golden heads some time in September. I regret to say, however, that it is only now, in mid-October, beginning to show colour, too late to be of any service. I should be glad to hear what the experience of others has been with this plant, either north or south of the Tweed.—CALLEDONIA.

Saxifraga burseriana in Scotland.—My experience with *S. burseriana* may be of interest to those who are perplexed by the accounts of its habitat in a Swiss gorge and who may fear to try it at home. It appears to be not at all a difficult plant, either as regards soil or situation. Many years ago I planted a large clump from a 6-inch pot into a border along with other hardy flowers, and there it remained with the aid of an occasional dusting of fine soil till a year ago, when it was transferred to a rockery at that time reconstructed. It was placed where the sun shone on it from early morning till two or three o'clock in the afternoon, and is certainly none the worse-looking for being shifted. It is growing in ordinary loam, and a few weeks ago, with other Saxifragas and dwarf plants, was dressed with the usual fine soil I am in the habit of applying periodically to these plants. From the way they respond I have come to regard these dressings as a very important item in the cultural treatment of low, close-growing alpine, and have for long made it a routine practice.—R. P. BROTHERSTON, *Tynninghame, Prestonkirk, N.B.*

Lilium giganteum in Yorkshire.—A native of the mountainous regions of Northern India, this handsome Lily reaches a high standard of excellence in favoured places in this country. We have had fine specimens in flower this summer growing in a spot almost surrounded by large trees, two Yews on one side making an admirable foil. Several spikes of about eight feet in height, containing from eight to twelve large blooms, were to be seen flowering towards the end of July and lasting for about three weeks, filling the air with their fragrance for some considerable distance. The bulbs were planted three years ago in a prepared bed of loam, &c., have not since been disturbed, and this is the first time of flowering. Each season good, healthy growth has been forthcoming. During the dry spell this summer the bed received a few good soakings of water, and a liberal mulching of farmyard manure was also applied. No one who has had the pleasure of seeing *Lilium giganteum* in its full beauty can fail to give it a trial, for its noble grandeur adds distinction to any garden. In choosing a position, one should be selected, if possible, sheltered from the north, and anything approaching a stagnant soil should be avoided.—H. TURNER, *Scotby Hall Gardens, Bastry, Yorks.*

The Daffodil in New Zealand.—A correspondent has just sent me a cutting from the *New Zealand Herald* of August last, giving an account of the Auckland Daffodil Show, which appears to have been a very successful function. It quotes a speech made by the judge (whose name is not given). I quote from it. "The seedlings," he remarks, "have some very good blooms among them, and to-day's display in this section makes one extremely dubious about buying plants from Home." This is a little unkind to Messrs. Barr, who were given a cup at the show. He proceeds, "Although Home nurserymen may produce a few seedlings of better quality than those grown in the Dominion, I think the New Zealand average seedling is better than the Home plant." All this makes very sad reading for the Old Country. *Sic transit Gloria Mundi, sic transit Bernardino* and all the good things we have prided ourselves on; and no doubt after this Mr. Engleheart, Mr. Croshold and humble followers of them like myself and others will give up any further work and leave off wasting our time.—F. H. C.

A NEW PLANT FERTILISER.

DURING recent years, owing mainly to the increasing difficulty experienced in obtaining natural manure, scientists have devoted considerable time and thought to the question of fixing the free nitrogen present in the air so as to render it available for use by green-leaved plants. As any student of botany is aware, many plants belonging to the Pea family, such as Beans, Peas and Clover, have on their roots little swellings, technically known as nodules, which contain bacteria that are capable of extracting this free nitrogen from the air and so converting it that the plants, and also those that follow them, are able to make use of it. It was argued some years ago that if these bacteria could be artificially added to the soil in sufficiently large quantities, and induced to carry on their work, plant-life generally would be considerably benefited thereby. Then came Professor Bottomley of King's College, London, with a culture that he called nitro-bacterine, and for which he claimed that it would, if properly treated, inoculate the soil with sufficient bacteria to render the application of artificial nitrogen unnecessary. Time has proved that this did not, under practical conditions, do what was claimed for it. Now, Professor Bottomley comes forward with inoculated peat. At the Horticultural Club on Tuesday of last week the Professor gave an exceedingly interesting lecture on the subject and proved beyond all doubt that, whatever may be the reason, the application of this prepared peat has a very marked effect on vegetation. Briefly, the peat is treated with aerobic bacteria to destroy the injurious humic acid that it contains. Next it is sterilised by steam, and finally inoculated with a pure culture of nitrogen-fixing bacteria.

Experiments have been conducted in various parts of the country with this inoculated peat, but two instances will suffice for our purpose at present. One experiment—and the most important to horticulturists—has been conducted at Kew. Here the curator, Mr. W. Watson, has personally supervised the work, and those who are privileged to know him are fully aware that he has little faith in scientists of any kind, and would be only too glad to be able to condemn

their theories. Two each of plants of widely diverse characters, such, for instance, as *Abutilons*, *Fuchsias*, *Salvias*, *Hippeastrums*, *Asparagus plumosus* and *Maidenhair Ferns*, were selected, one of each being grown in ordinary potting soil and the other in potting soil to which the prepared peat had been added, in proportions of one part peat to two of soil, one part peat to four of soil, and one part peat to eight of soil. The plants had been brought from Kew for members of the Club to see, and in every instance both root and stem growth of those growing in the peat-charged soil was very much better than that of those grown in ordinary soil. Mr. Watson, who addressed the meeting at the conclusion of the lecture, stated that he had no doubt whatever that the prepared peat, when added to the soil, had a highly beneficial effect on the plants. He also stated that when used at its greatest strength, *i.e.*, one part of peat to two of soil, it had no injurious effect on vegetation, yet the one part of peat to eight of soil mixture gave just as good results.

The other experiment has been conducted by Mr. Peter Lees, the well-known authority on golf greens. Unfortunately, this was not made known until the close of the meeting, when many members had left. Apparently Mr. Lees has been using this prepared peat at the rate of 3oz. per square yard as a top-dressing to badly worn or thin greens, with a result that is little short of marvellous. Not only was new top growth made in abundance, but roots also of a fibrous and far-reaching character were formed. If this were all, it would seem that we have a panacea for all the troubles that beset the grower of plants. But Dr. Voelcker rather put a wet blanket on the enthusiasm of those present when he asked the pertinent question whether the benefit was due to the nitrogen-fixing bacteria or to the plant food that peat naturally contains, and which would be rendered available by eliminating humic acid and by sterilisation, and to the mechanical effect that peat would have upon soil used in the proportions named. Dr. Keeble, who also had something to say on the subject, supported Dr. Voelcker's statement that probably sterilisation of peat by steam would have a greater beneficial action upon it than the inoculation with nitrogen-fixing bacteria.

The question of cost in producing this prepared peat was raised by several members, but on this important point Professor Bottomley would not express an opinion. If it can be produced cheaply—which we very much doubt—it will certainly prove a boon to the gardener, no matter whether its beneficial action arises from the natural manurial substances that peat contains or from the nitrogen-fixing organisms. Meanwhile, we must wait and see.

FORTHCOMING EVENTS.

November 4.—Royal Horticultural Society's Exhibition at Vincent Square, Westminster. Sevenoaks and West Kent Chrysanthemum Show (two days). Plymouth Show (two days).

November 5.—National Chrysanthemum Society's Show at the Crystal Palace (three days). Autumn shows at Stoke Newington, Undercliffe, Guildford, Barry, Bromley, Northampton, Bideford, Tottenham (two days), and Highgate (two days).

November 6.—Devon and Exeter Show (two days). Shows at Weston-super-Mare, Newport (Monmouth), and Bury.

November 7.—Shows at the Corn Exchange, London; Huckleley, Eccles, and Kirkcaldy (two days).

November 8.—Shows at Loughborough, Wood Green and Farnby.

ROCK AND WATER GARDEN.

SOME INTERESTING FACTS ABOUT GENTIANA VERNA.

FEW of the alpine flowers which decorate our gardens during April and May have such a charm, both for daintiness of outline and intensity of colouring, as the Vernal Gentian. While seeming to revel in the moist atmospheric conditions prevailing in many parts of Ireland, it is not often that *Gentiana verna* is seen at its best in the Eastern Counties of England, where, during the early spring, we frequently experience dry, cutting winds from the north-east. These arid conditions, which so rapidly cause our Ranunculus to turn brown and curl upwards, are, I believe, responsible for much of the difficulty we experience with some of our mountain plants, especially as the sodden condition of our normal winters induces the plants to be constantly active, instead of being at rest during the chill time of the year.

So many plants are "hardy" while dormant, and, again, many more are immune from the frost so long as they are comparatively dry; but when wet and cold jointly act upon them, the result is often fatal, or at least considerably reduces their vitality.

It occurred to me some years ago that these unhappy conditions could to a large extent be modified by inducing the plants to go to rest at the end of the autumn, and a sheet of glass somewhat larger than the patch or tuft, placed above it and supported upon three or four bent wires, formed a ready means of throwing off all rain, while a slight tilt to one side allows the water to drip off on to some pre-arranged stone, thus avoiding any damage to neighbouring plants. This sleep-inducing system proved so far successful that I have for several years past, despite the smoky condition of my neighbourhood, been favoured with a pleasing display of the "blue stars" of *G. verna*, among other alpine subjects, which I treated in this way.

To illustrate as certainly as possible and so check off the value of this "dodge," I made the following experiment, commencing in the spring of 1912 by planting two small patches of *G. verna* in as nearly similar positions as possible, and both in a compost of loam, leaf-mould, chips, sand and old mortar in roughly equal proportions, the aspect being full south, and both kept copiously moist from the end of March to September.

In November, 1912, I placed a root glass over Patch A, while I allowed Patch B to go unprotected. With the exception of occasionally cleaning the glass, no further attention was given to either. In early March the glass was removed from A, which then looked dry, close in habit and healthy, though no flower-buds were showing, the whole plant appearing dormant. At the same date (early March) Plant B was well "on the move," looking fresh and much more pleasing than its competitor A, and not appreciably harmed by the wet winter, so far as growth was concerned, while four or five of the points were "bronz-

up," as the flowering crowns do as the buds form. On March 30 Plant A was rapidly developing, and all the points looked as if about to "push" into flower-buds, while fifty of such buds were actually showing. Plant B at that date was swelling its twelve flower-buds almost to bursting point. On April 16 Plant B opened its first flower and had increased its buds to eighteen. On April 18 Plant A opened its first flower, showing how rapidly it had developed after its more complete rest, catching up Plant B to within two days. The fifty buds of March 30 had increased to 150. On April 20 Plant A exhibited a number of opened flowers of dazzling blue, while the total number of blossoms and buds stood at 105. On April 27 Plant B had all its eighteen flowers open, and this was the limit of its production.

On the same date I made the last count on Plant A, a difficult matter where the buds were set so thickly as almost to touch one another.

GENTIANA VERNA FLOWERING FREELY AFTER HAVING BEEN COVERED WITH GLASS IN THE WINTER.

By placing pieces of string across the patch (which was some 10 inches square) it was easily cut up into sections, and each section counted accurately, the total numbering 206. When first planted in 1912 the Patches A and B were approximately the same size. By the summer of 1913 A had doubled B, suggesting that it was more vigorous in growth as well as in flower production.

From the foregoing I think it must be admitted that the root glass appears to increase the proportion of flower and the general health of the plant, not merely with this test subject, *G. verna*, but with very many of our choicer alpine plants, while if, as some of my critics may suggest, the beautiful display was unconnected with the treatment, the glass protection does not greatly harm the plant.

R. A. MALBY.

THE ROSE GARDEN.

IN A HAMPSHIRE GARDEN.

NOTES ON NEWER ROSES.

(Continued from page 540.)

Claudius (B. R. Cant and Sons, 1910).—A Hybrid Perpetual-like Hybrid Tea with most of the characteristics of the first-named class, including a marked cessation of flowering between the seasons; but it comes good again in the autumn, and is fragrant. It was at the autumn show of 1909 that it secured the gold medal. Those who do not grow it might give it a trial. At its best it is quite up to exhibition standard, and is at normal prices.

Countess of Shaftesbury (Hugh Dickson, 1911).—A Rose of delightful colour and shape, but on the thin side, and only the "first" flowers are up to exhibition standard. Silvery carmine and shell pink describes its colour. Its growth is moderately vigorous. A very beautiful Rose that must have the best of cultivation to get substance into it.

Colleen (S. McGredy and Son, 1914).—I was hoping this Rose would be distributed this autumn, but we shall have to wait until next year for it. Awarded the silver-gilt medal at Belfast, and the gold medal this year at Gloucester. Its great shield petal is very fine. Colour, flesh pink on a cream ground. A good grower and very free-flowering, and the flowers always come a good shape. What a great boon this is to the exhibitor, only one who has exhibited knows. How many a fine bud is nursed and tended, protected and shielded from sun and rain, only to prove that when it opens it is of no use, with a great split that spoils its beauty alike for the exhibitor and the exhibition. And it is Roses like Colleen, which seldom develop such a fault, that are so useful to the small exhibitor in particular whose space is limited. Colleen has done well in my garden here, and is a very great advance on Killamey, to which some critics liken it. The raiser is very proud of it, and considers it one of his best introductions. While it is not mildew-proof, it does not suffer like many other Irish Roses from this disfigurement. It is a fine, vigorous grower of good constitution.

Duchess of Normandy (Philip le Cornu, 1912).—This has been particularly good with me this year. It is quite as good a grower and doer as its parent, Dean Hole, and the early season flowers were first-rate in every respect, especially in colour. The autumn flowers missed the sun, perhaps, and this feature was not so marked; but it is very free-flowering, and my plants are now, in mid-October, full of bud and bloom. It has the fault of its parent that it is impatient of wet; but that has no terrors for the keen exhibitor. I can recommend it to all who have not got it, and I do so all the more because I do not think that our cool season has altogether suited it. It will be at its best in a hotter and drier season than the last.

Duchess of Sutherland (Alex. Dickson and Sons, Limited, 1912).—This is a well-built-up flower of fine shape and nice clear colour—rose pink of

an unusual shade. It is a fine, vigorous grower, almost mildew-proof, and generally of good habit. The blooms are large, but at the same time conical in shape, and this shape is never lost, its centre being retained until the petals drop. This Rose has a strong Sweet Briar perfume that is very noticeable.

Duchess of Westminster (Alex. Dickson and Sons, 1911).—This Rose appeals by reason of its somewhat unusual outline, and when you dissect to find the reason, you notice that the petals are very much cut away at the base. The result is quite unique. At the same time, it is perhaps not everyone's fancy as an exhibition variety, as it lacks that look of "weight" that counts so much with some judges. It has, however, an excellent point—with me quite a good grower, though I see some catalogues call it moderate. Good foliage, delicious perfume, and lasts well when cut. Colour, rose madder pink. The buds sometimes come rough, but they open into good-shaped flowers.

Earl of Gosford (S. McGredy and Son, 1912).—A strong, vigorous grower this, that has been much freer-blooming as a cut-back. The flowers are a wonderful colour—dark crimson, several shades darker than Hugh Dickson—and they keep their colour to the last. There is none of that nasty blue tint which spoils so many dark crimsons. Strongly perfumed and of good shape, cupped rather than reflexed. Must be disbudded to get to exhibition size. Particularly good in the autumn.

Edward Mawley (S. McGredy & Son, 1911).—This Rose has improved this year, and has distinctly enhanced its reputation. A good many blooms have found their way to the exhibition tents and were staged. The previous year they were mostly left in the spare boxes. Its colour will always make us stage it, if we can. It has not too many petals, and directly the outside row or two are opened, the Rose goes, so it must be cut and staged young. Highly perfumed and with a good habit of growth. It evidently prefers a cool season. Everyone was glad to see it doing better, if only for the sake of the name it bears.

Elizabeth (B. R. Cant and Sons, 1911).—A genuine pink Druschki this, with more petals and, consequently, a harder centre. It produces a fine pointed flower, its only fault being that the outside petals are not quite big enough. Very free-flowering and reliable. Must be heavily disbudded, and is strongly recommended to the exhibitor.

Ethel Malcolm (S. McGredy and Son, 1910).—This Rose is almost too free-flowering to produce exhibition flowers, except in the early part of the season from cut-backs; from maidens it is a different matter. It is flesh colour, almost maiden blush tint, sweetly scented and a good grower, not too vigorous, and therefore makes a very fine bedding Rose. It was to be seen at most of the early shows, but not afterwards, which, being interpreted, means that it should be useful to our Midland friends and the Northern growers who want early Roses.

A SHOWY CLEMATIS FOR THE FLOWER BORDER.

C. JUBATA

THE accompanying illustration of this plant directs attention to a decorative group of herbaceous species which are typified by the Southern European *C. recta*. *C. jubata* resembles the better-known species very closely in habit and general appearance, although rather stronger, with larger flowers. Growing to a height of 2½ feet or 3 feet, it bears long leaves divided into seven or less ovate or heart-shaped leaflets which are glaucous when young. The white or cream-colored flowers are borne in large terminal panicles during June, their presence being noticeable from a considerable distance by reason of their fragrance. Although

CLEMATIS JUBATA, A BEAUTIFUL SPECIES WITH DWARF, BUSHY HABIT AND WHITE FLOWERS.

described as long ago as 1849, there is a mystery as to its origin, for its native habitat is unknown. As *C. recta* is a variable plant, it is probable that it is little more than a strong-growing form of that species. Whatever its affinities, it is a very decorative plant, and is well worth attention from those people who wish for showy, hardy plants for herbaceous borders. Given ordinary deep garden soil it grows freely, and never fails to flower well. Division of the clumps during winter forms a ready means of increase, while young plants may also be raised from seeds. As will be seen from the illustration, growth is very dense, and it is sometimes an advantage to cut out the weakest shoots during the growing period, thus admitting light and air to the stronger ones that are left. Although not a climbing species, this Clematis appreciates the support of a few short Pea-sticks thrust well into the soil.

THE BEST TREES FOR AVENUES.

THE selection of trees for avenue planting is a subject which cannot be dealt with lightly, for it must be remembered that such an avenue may exist for two or three centuries, and every possible contingency must be considered before finally deciding upon the kind of tree to plant. The character of the soil, the room which can be allowed, atmospheric conditions, proximity to towns and climate are all subjects which demand attention, for the neglect of any one may lead to failure.

Unless the avenue is to be a short one, entailing comparatively little work and expense, it is unwise to select a tree about which little is known, simply because it is new or rare. About the middle of last century many avenues were formed of new or rare coniferous trees, and comparatively few of them have developed satisfactorily. As a rule it is wise to note whether a particular tree

thrives well in a certain district before it is selected for an avenue; but, at any rate, it should be ascertained whether the local conditions are likely to suit the tree. For instance, it would be unwise to plant conifers near a smoky town, on a very dry soil, or in a district where atmospheric conditions are decidedly on the dry side. On the other hand, coniferous trees would be more suitable than broad-leaved trees for the most climatic conditions and moist ground which are so often in evidence in the South and West of England, many parts of Scotland and in Ireland.

Another point which deserves more attention than is often paid to it is the spacing of the trees, not only in the rows, but between the rows. When laying out the ground, the trees must be considered as mature specimens, not as young plants, and arrangements made accordingly. Many an avenue has been spoilt by being made too narrow, thus

allowing no space for the proper development of the trees. The space between the trees in the rows is less important than the space between the rows, for it is always possible to thin them out, by removing every other tree, if they become too thick. With wide-headed trees a rough guide as to the distance between the rows may be ascertained by measuring off the space required for the heads of two perfectly-developed trees, or the average height of one well-grown tree, as the centre of the avenue; then on each side measure back half the diameter of the mature head to find the positions for the trees. Between the trees in the rows, when fully developed, there should be a space of at least half the width of the head of a tree. In the event of a double row of trees being planted along each side, the trees must be further apart in the rows, and those in the two rows should be alternated.

If the soil is poor, holes at least 8 feet in diameter and 2 feet deep must be taken out, and either filled with new soil or have better soil mixed with the best of the natural soil. This work should be done and the holes filled in at least two months before planting-time, for if the trees are planted on the loose soil, there will be considerable sinkage and the lower parts of the trunks may become buried. Keeping the top roots quite close to the surface of the soil is a very necessary item, for if the trunk is buried even to a depth of 3 inches or 4 inches, the tree rarely succeeds so well as one which is planted properly.

SELECTION OF TREES FOR WIDE AVENUES.

The Horse Chestnut (*Aesculus Hippocastanum*) is one of the best avenue trees for places which are not seriously affected by smoke, for its massive head, clothed with large, ornamental leaves, coupled with its fine inflorescences of showy flowers, makes it a general favourite. It is not very fastidious regarding soil, but prefers a fairly deep loam. The double-flowered form is preferred by some people, as it does not produce fruit.

The Elms (*Ulmus montana*, *U. glabra* and *U. campestris*) are all worth attention, and are very imposing when mature. Their only drawback lies in the fact that old trees are very brittle, and large, perfectly healthy branches are liable to fall without warning, even on a calm day. Where space is limited, the narrow-headed, upright-growing Cornish and Hertfordshire Elms should be chosen.

The common Lime (*Tilia vulgaris*) is often chosen as an avenue tree, but in most cases it would be wiser to select *T. dasystyla* or *T. petiolaris*, for they are more handsome trees and the leaves do not turn yellow so early in autumn. The mistake of allowing the trees to branch too near the ground is often noticeable in the Lime.

The common Oak (*Quercus pedunculata*) forms a handsome tree for avenue planting, but it should

only be used in places where there is a good depth of rich, loamy soil; otherwise it will fail to do itself justice. The Durmast Oak (*Q. sessiliflora*) may also be used, and such kinds as *Q. coccinea*, *Q. palustris*, *Q. rubra*, *Q. conferta* and *Q. Mirbeckii* are also worthy of consideration.

The common Beech (*Fagus sylvatica*) may be relied on to form an imposing avenue, but it is unwise to use it in very exposed positions, for if subjected to rough and cold winds its full proportions are not attained. For special positions the purple and copper leaved kinds may be tried.

The Sycamore (*Acer Pseudoplatanus*) is worth planting in districts where the tree grows to its

nigra (the Black Walnut) and *Platanus orientalis* (the Oriental Plane) are other broad-leaved trees which may be used from the Midlands southwards.

The Maidenhair Tree (*Ginkgo biloba*), although not used except as an isolated specimen, is likely to give good results as an avenue tree in places where conifers thrive. Could an avenue of this be established, it would form both an uncommon and interesting feature.

Other conifers which are worth attention are Scots Pine (*Pinus sylvestris*), Douglas Fir (*Pseudotsuga Douglasii*), *Cedrus atlantica* and its glaucous variety, *Cupressus lawsoniana* and *Tsuga mertensiana*. Where space is limited, smaller trees, such as *Prunus Avium flore pleno*, double-flowered Thorns, *Pyrus Aucuparia*, *Fraxinus Ornus* and *Aesculus carnea*, may be planted. K.

A HANDSOME BORDER CAMPANULA (*C. LATIFOLIA ALBA*).

FLOWER GARDEN.

THE CAMPANULAS OR BELLFLOWERS.

(Continued from page 536.)

BORDER CAMPANULAS.

WHILE the gems of the race belong to the Campanulas most suitable for the rock garden, a considerable number of the border species are of commanding value for the garden. As a rule, they can be successfully cultivated in the ordinary border of common loam, but the greater number are the better for good soil and supplies of manure at intervals. They are easily raised from seeds sown in spring in the usual manner for hardy perennials, and the vast majority may be increased by division in spring or autumn.

C. alliarifolia.—Although rather coarse in its way, *C. alliarifolia* is a good border plant, with rather cordate leaves, pilose on the surface. The drooping white flowers are in neat spikes. It is occasionally grown as *C. lamifolia*, *C. cordata* and *C. cordifolia*, and from some nurseries a variety of *C. latifolia alba* is sometimes sold as *C. alliarifolia*. About a foot high. June and July.

C. amabilis.—A pretty Campanula with a tuft of glossy leaves near the level of the soil, and spikes from 12 inches to 36 inches high of pleasing blue flowers in July. I have found this difficult to retain,

as it often flowers itself to death, but this is not the universal experience. Seeds or division. *C. phytidocalyx* resembles this.

C. americana.—This is not a very desirable subject, being either biennial or annual, usually the former, and coarse in its way. It likes partial shade and moisture, and grows from 2 feet to 6 feet high. It has spikes of blue or almost white flowers in July. Seeds.

C. bononiensis.—About a foot high, this is a useful July-blooming, starry-flowered blue Campanula, but one which wants frequent propagation

largest size; but where it only attains medium proportions, some other subject is more desirable.

The common Tulip Tree (*Liriodendron tulipifera*) might be used in the Midlands and Southern Counties where the soil is good, for it grows freely in most gardens, is an imposing tree and uncommon for the purpose.

The Hobn Oak (*Quercus Ilex*) thrives well in many parts of the country, and may be used for avenues in the South and West. A fine avenue of this tree occurs at Tregothman in Cornwall. *Alantus glandulosa* (the Tree of Heaven), *Juglans*

to keep, as it seems to exhaust itself. Seeds or division. Common soil. Alba is a white variety.

C. Burghaltii.—A handsome hybrid 12 inches to 18 inches high, with very large, drooping bells of light purple in July. Easy to grow in any border, and also pretty on large rockwork. Division. It is rather lighter than *C. van Houttei*.

C. elegans.—The plant the writer has grown as this is from 2½ feet to 3 feet high, and has rather toothed leaves and spikes of pendent blue flowers in July. It was troublesome, running at the roots, and was discarded. Seeds or division, and flowers in July.

C. Fergusoni.—A handsome hybrid 2½ feet high, with pale blue, cup-shaped flowers. Common soil. Division. July.

C. glomerata.—The Clustered Bellflower is a valuable border species, well known for its clustered

C. Hendersoni.—A hybrid of much beauty, after the fashion of a small Canterbury Bell, but perennial. Neat growth, about a foot high, and with nice blue bells on short spikes in July. Division.

C. lactiflora.—This is a truly handsome plant for large borders of good soil, and grows from 3 feet to 6 feet or 7 feet high. It has rather flat heads of flower, varying from purple to white, and there is a variety with very starry flowers. Poor in dry soil. Seeds or division. The same as *C. celtidifolia* of gardens. June, July and August.

C. latifolia. This handsome June and July flowering native plant, 3 feet to 6 feet high, should be represented in gardens by *C. l. macrantha* and *C. l. m. alba*, two superior forms with larger bells, and the first more richly coloured than our blue *C. latifolia*. The flowers are a rich purple. Good

margin of the lake at Kew. The remarkable thing is that this Iris is not more widely grown. Frequently one sees a pool or lake the margins of which could be made far more beautiful if fringed with the Siberian Iris.

TULIP NOTES.

Bedding Suggestions.—In all bedding arrangements we want to "eat our cake and have it" as much as possible; in other words, we are greedy for a long display on the same piece of ground. We want it now and we want it again. There are two simple ways of doing this with Tulips. One is to place Daffodils and late-flowering Tulips alternately in a row in a rectangular, or in a circle on a round, bed. This last spring I had *Mme. de Graeff* and *Ellen Willmott* thus planted. On a former occasion I had *Seagull*

THE SIBERIAN IRIS BY THE WATERSIDE.

heads of upright flowers. It varies from blue and purple to white, and is from 6 inches to 18 inches high. *C. g. acanthis* is a curiously pretty little plant for the front of the border or the rockery. *C. g. dahurica* is one of the best, and there is a double variety. Common soil. Seeds or division, June onwards.

C. grandis.—Another of the best border plants, making tall spikes from 12 inches to 30 inches high, with saucer-shaped flowers of blue or white in good spikes. Sometimes makes too much foliage and requires division. A capital border plant. It is now known as *C. latifolia*. June to July.

C. Grosseki.—A tall plant 2½ feet to 3 feet, with coarse leaves and spikes of blue flowers. Not a choice species. Seeds or division. July.

soil, and partial shade is preferable. Seeds or division. *C. eriocarpa* is a rather woolly form of this.

S. ARNOTT.

(To be continued.)

THE SIBERIAN IRIS.

IRIS SIBERICA is one of the most graceful of the numerous water-side plants that flower in June. Although a moisture-loving plant, it prefers not to be planted in water, but rather on the margin of a stream or lake. It is a sun-loving plant, but is not in the least fastidious about soil. Sometimes it may be seen flourishing over a light, gravelly soil, and at other times over a clayey loam, but it always does best with its roots near the water's edge. The illustration shows clearly the charming effect created by this Iris on the

and Mrs. W. O. Walseley, but there is no need to say more, for any Daffodil and any late Tulip will do equally well. In this arrangement the one thing to remember is to cut off the stalks of the faded Daffodil blooms within a few inches of the ground. Just pulling the heads off is the "anything-will-do" way. What I have said ought to be done is the satisfactory plan. The rigid stems which the lightning executioner leaves behind are a jarring note when the Tulips bloom, even to an untramed eye.

The second way to make the same bit of ground do for both is to plant a cheap early Tulip alternately with a late one, and then, when the former have finished blooming, to cut them all off at the ground-level, so as to allow the taller and later flowerers more room to shake themselves out and to avoid

the squashed-up appearance that otherwise the leaves would have. It is a curious thing, but this last most obvious plan is not my own at all. A lady visitor to my garden told me about it and assured me that it worked splendidly.

From another visitor I picked up last spring the idea of an uneven bed—deliberately planned and planted to come up as such. Yet what is this but that which the Branching Tulip of M. Bony gives us. I had a most satisfactory round bed in my garden last spring. So many were the nice things said about it that it blushed and blushed and blushed, until what once was an ivory white became almost all rose, for, unlike humanity, the old hardened sinners were the blushers here, while the younger did not appear to be affected for a considerable time by what they heard. Think, then, of the idea of an uneven bed. It has many possibilities.

The Rage for Purples and Mauves.

—If to the above sub-heading I were to add rich browns and brownish yellows, I think I would hit off the popular taste of 1913. Once it was all Clara Butt; now it is The Bishop, Velvet King, Faust, Zulu, Viking, Jubilee, Viola, La Tristesse, Bleu Aimable, Morals, Euterpe, Rev. H. Ewbank, Erguste, Bleu Céleste, Gudin, Crépuscule, Thérèse Schwartz, Frans Hals and such like; while among the browns and brownish oranges and yellows it is Clio (Bronze Queen), Gondvink, Toison d'Or, Apricot and Jaune d'Œuf. Every one of these that I have jotted down is a grand variety, and there are other good ones too, for I have by no means exhausted the list. Some that I have mentioned are "excessively," as the old book-lists say, scarce. The Bishop (blue-purple) and Gondvink (tortoiseshell and orange), for example, are probably now unobtainable. Excluding such as these, I am going to end these notes with a list of a few that probably will please me out of every ten people who buy them. *Not all*, for the principle of one man's meat being another man's poison is both objectively and subjectively true. Everyone does not like the same thing. So here goes. Very deep rich plum purples: Zulu (extra tall) and Morals (covered, as it were, with "bloom"). Red purple: Frans Hals (magnificent, in two shades), Ascanio

dwarf plant, long, delicate-looking bloom of a lovely pale mauve), Bleu Aimable (striking open shape, much blue in the mauve shade; to me very beautiful), Euterpe (tall and stately, a veritable queen among the paler mauves or blues; in the full-blown flower the lavender edges of the petals curl in, which gives it a distinct and pleasing appearance). Browns: Cho (tall grower, immense flower of the colour of a nicely-baked biscuit), Toison d'Or (medium height, rich golden bronze and brownish orange; richness personified), Jaune d'Œuf (a round flower with a lemon yellow ground and brownish orange shading), Gondvink (the counterpart of Cho in tortoiseshell and orange; a truly magnificent flower). One word to conclude:

to boot. The colour is of intense crimson, the velvety sheen upon the petals adding lustre to a very fine flower. The reverse of the petals is light golden. A notable quality is the crispness or firmness of the petals, that type of hardness which the cultivator knows will make it endure. In other words, it will prove a good keeper. From Messrs. Wells, Limited, Merstham. See illustration.

Chrysanthemum Amy Poulton.—A Japanese of the drooping type of exhibition flower. The predominant shade of colour is pale pink, with a certain degree of yellowing or creaminess in the centre. From Mr. H. Poulton, Ware, Herts.

Carnation Cinderella.—A rather bright-looking and attractive variety, best described perhaps as an heliotrope fancy, if such a class or section exists, which we very much doubt. This is suggested rather by the mingling of heliotrope and scarlet, the latter being responsible for the greater attraction of the flower. From Messrs. G. Fairbairn and Sons, Carlisle.

Cattleya Empress Frederick Variety A. Clifton (C. Mossie × C. aurea).—This is a distinct form, with white sepals and petals, and a creamy lip which is marked with gold and purple. From P. Ralli, Esq., Ashted Park.

Cattleya graniris (C. Iris × C. granulosa).—A grand acquisition, with chestnut-coloured sepals and petals, and a crimson lip which is well displayed. From C. J. Phillips, Esq., Sevenoaks, Kent.

Oncidium varicosum Weston-birt Variety.—This is a much larger form and bright yellow in colour. From Sir G. Holford, K.C.V.O.

Sophro - Cat - Lælia Laconia (Lælia-Cattleya callistoglossa × Sophro - Lælia heatonense).—A dwarf plant with two scapes of rosy red flowers and a little more crimson in the lip. From Messrs. Charlesworth and Co., Hayward's Heath.

Cypripedium Queen Alexandra (C. lathamianum × C. Charlesworthii).—A large, but not a very attractive flower. The dorsal sepal is white at the apex, and the lower part is green and rose. Exhibited by W. R. Lee, Esq., Heywood.

Odontoglossum Vivien.—Very similar to a good O. crispum, the segments being almost white, with red blotches and markings. From Sir G. Holford, K.C.V.O.

THE NEW CHRYSANTHEMUM WILLIAM VERT. OF INTENSE CRIMSON COLOUR.

The foregoing selections exhaust my space but not my "fancy."

JOSEPH JACOB.

NEW AND RARE PLANTS.

AWARDS OF MERIT.

Chrysanthemum Mrs. R. C. Pulling. A large and handsome Japanese incurved variety which also possesses the good attribute of refinement. It is said to be an easy doer. The colour is rich buttercup yellow. From Messrs. H. J. Jones, Limited, Lewisham, S.E.

Chrysanthemum William Vert.—A Japanese of the reflexing type, and of good exhibition size

NEW FRUIT.

Apple S. T. Wright.

A large, bright, culinary Apple of excellent cooking qualities. The tree is of good habit and a heavy cropper. Season: October and November. The fruit is somewhat flat, with a broad base, and the stalk set in a deep cavity. On the sunny side the fruits are highly coloured, with yellow and carmine splashes. Flesh, cream coloured and soft; core small. Small fruits are quite pleasing for dessert. Parentage: Bismarck × Peasgood's Nonsuch. An award of merit, now confirmed, was recommended at the previous meeting, subject to the cooking qualities of this Apple. Shown by Messrs. James Veitch and Sons, Limited.

GARDENING FOR BEGINNERS.

ROOTING CUTTINGS OF CURRANTS AND GOOSEBERRIES.

OCTOBER and November are the best months for taking cuttings of Gooseberries and Currants. Select well-ripened young growths. The cuttings when made should be from 9 inches to a foot long. For preference take off the cutting immediately below a joint. In the case of the gooseberries and

bearer of good-sized berries. Another good red is Crown Bob, while among the red sorts for flavour Red Warrington should be chosen. Langley Beauty is one of the best yellow sorts, free-cropping and of good flavour. Leveller has very large yellow berries, crops freely and ripens early. Gunnet is another useful yellow variety. Keepsake leads the way as a large-fruited green gooseberry, cropping heavily. For size Green London may be grown, and for early ripening Berry's Early Kent. Langley Gage must be regarded as one of the best white gooseberries, for it not only crops freely, but is of excellent flavour. Whitesmith is another white sort notable for flavour and general good qualities, unless it is another useful sort with white fruits.

Red Currants. Fay's Prolific, Red Dutch, Ruby Castle, and Le Comte, a very good late sort for a north fence.

White Currants. White Dutch and White Versailles.

Black Currants. Baldwin's, Beskoop, Giant (very large berries) and Lo's Prolific (good flavour).

Currants and Gooseberries will grow and fruit well in most soils if the soil is thoroughly trenched before planting. The best soil is a deep, medium loam. Heavy soils may be improved by working in, when trenching, plenty of old mortar rubble, leaf-mould and wood-ashes. If very heavy and wet, it is worth while removing the soil to a depth of 2 feet, putting in 4 inches to 6 inches of brick rubble for drainage and filling up with 18 inches of prepared soil, say, about two-thirds of the natural soil and one-third of material to lighten it. Light soils are improved by deep cultivation and manuring, using cow-manure for preference; also, if available, adding a few barrow-loads of good top-spit turfy heavy loam.

Positions and Shape of Trees.

—What are known as bush trees are those in general favour. In small gardens, however, where space is limited, the trees may be planted against a fence or wall with distinct advantage, for not only are the fruits easier to protect, but it is more convenient, and they are, as a rule, larger and better in quality. The aspect of the wall or fence does not matter, except that if two aspects can be chosen, including one facing north or north-west, the season of ripening is considerably prolonged. To plant against a wall or fence, nurserymen train special trees limited to one, two or three upright growths; these are known as cordons. Gooseberries and Red and White Currants are trained in this form; but Black Currants, which fruit on the young wood of the previous season,

if planted against a fence, must have a liberal supply of these young shoots left.

HOW TO TREAT GREENHOUSE CLIMBING PLANTS.

In the autumn, greenhouse and conservatory climbing plants need very careful attention, as they often grow rapidly. They cover the roofs, and, owing to the declining light and sunshine, it is necessary to reduce the mass of growth for the benefit of plants growing on stages under the eaves as well as for the welfare of the climbers themselves. The climbers that are chiefly referred to here are Passion Flowers, Tacsonias, Bignonias, Phloxes, Fuchsias and Heliotropes. Indiscriminate pruning of the branches of these plants would result in damage to them next year.

The Passion Flowers and Tacsonias must be thinned out pretty freely. The shoots of the other kinds must be pruned back one-third of their length now. In December one-third more must be cut off, and in February the final pruning should be done. The last pruning will be close, similar to that done when Grape Vines are finally pruned. At the time when the first pruning takes place, a gradual reduction in the supply of water is necessary. As Christmas comes, very little water will be needed. In February the soil must receive a thorough soaking of clear water. Top-dressings and manure-water will be needed as the new shoots make progress. If hard pruning was resorted to in the autumn, new shoots would grow prematurely, and the display of blossom next summer would suffer in consequence. B.

GOOSEBERRY CUTTINGS READY FOR INSERTION. IN THE CENTRE IS A SUITABLE CUTTING UNPREPARED.

Red and White Currants, remove all the buds in the axils of the leaves except three to five at the top of the cutting. Take out narrow trenches a foot apart and 6 inches deep, as illustrated. In the bottom of these place a little leaf-mould and sand, and insert the cuttings in this 6 inches apart and about four inches deep. Tread the soil firmly round the cuttings, and spread over the cutting-bed a layer of half-decayed leaves, some 3 inches deep, as a protection against frost in winter. The buds need not be removed from the cuttings of Black Currants, as young basal growths from time to time are very useful to take the place of old shoots which it is desirable to cut out. Late October and the first half of November is the best time to plant the young trees, though the work may be done during open weather until the end of March.

Selection of Varieties.—The growing of named sorts of Currants and Gooseberries is by no means a common practice. This is apparently due to the fact that the old bushes fruit satisfactorily, so why worry; and when young plants are required, cuttings are taken off the old bushes. Anyone, however, who has seen an up-to-date collection of named Gooseberries will not be satisfied if his own selection of sorts has been neglected.

Gooseberries.—Whinham's Industry is one of, if not the best of all the red sorts, being a prolific

CUTTINGS ARE PLACED IN TRENCHES 6 INCHES DEEP WITH LEAF-MOULD AND SAND AT THE BOTTOM.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Pleasure Grounds.

Mowing-Machines.—Presuming that the season's mowing is over, all machines should be overhauled and thoroughly cleaned, afterwards oiling or greasing them well and storing where they are not likely to be in the way during the winter.

Turfing.—When patching has to be done, it is as well to get on with the work while the weather is open and where the new grass has a chance to get well hold of the soil. It left over till the spring, it often shows the patch the whole summer through, and this is hardly necessary.

Grass Verges.—In many instances these have to be renewed, and where they have been cut back with the edging-iron a few times, the paths will have gradually got wider, and probably are some 2 inches or 3 inches back from the water traps. In such cases it is as well to make up the soil 1 inch or 2 inches wider than is required, afterwards cutting the turf a foot back from the verge; and it this is brought bodily forward, it will make a very much better job than putting new turf on the outside, the new turf being put in at the back to fill up the gap. Such work takes a good deal of time; but it is a careful and neat workman is put on to it, it well repays for the labour.

The Rose Garden.

Planting.—For bedding purposes the following are particularly good: *Carmine*, *Lady Pirrie*, *A. R. Goodwin*, *Mme. Abel Chatenay*, *Betty*, *General Macarthur*, *Laurent Carle*, *Gustave Regis*, *Harry Kirk*, *Lady Hillingdon*, *Mme. Melanie Soupert*, *Marquise de Smety*, *Mrs. Peter Blair*, *Pharisäer*, *Prince de Bulgarie*, *Viscountess Folkestone* and *Richmond*. Though all the above are most beautiful as cut flowers, a few of the singles may be planted, especially for table decoration, and these include *Old Gold*, *Irish Fireflame*, *Irish Elegance* and *Red-letter Day*. Another good Rose, though not quite a single, for this purpose is *Margaret Molyneux*.

Dwarf Polyantha Varieties.—A few of these are especially useful for bedding purposes, and as they bloom practically the whole season through, they deserve more than passing consideration. *Orleans Rose* I look upon as far and away the best in its class, it being most vigorous in growth; it is free-blooming, keeps a good colour in all weathers, and flowers from May to December. *Jessie*, *Schneewittchen*, *Aennchen Muller* and *Katherine Zeimet* are all good. Before planting, the roots of all Roses should be carefully pruned, partially cutting back all very coarse roots, preserving the fibrous roots as much as possible. Loose and too deep planting often results in failure, and providing the soil is not too wet, the plants should be well trod in.

Established Roses. whether standards or dwarfs, might well have some of the top growths reduced a little to prevent them being blown about by the wind, and after a storm it is wise to go round the plants, treading the soil up to them wherever necessary.

Plants Under Glass.

Coleus thyrsoides.—This beautiful blue-flowering plant should be given a fair amount of room as well as plenty of light and air, or the growth and flower-spikes will become weak, the plant being of rather a soft nature. A little manure should be given as the flower-spikes appear, the pots by this time being usually very full of roots.

Roman Hyacinths that were potted early should now be rooted sufficiently to take out of the ashes. They should not be given too much light and air for a time, but kept shaded; this should induce the growth to lengthen somewhat. After a few days they may be given a little heat if the flowers are required as soon as possible.

Paper-White Narcissi may be treated similarly, and on no account must they be allowed to get dry at the root, or they may become blind.

Liliums.—Batches of *Lilium lancetatum* and *L. longiflorum* that may be growing on for Christmas and the New Year must be carefully treated, a nice even temperature of 55° by day and 50° at night suiting them well. Any undue forcing is apt to upset the flower-buds at this season.

On bright days a slight dewing over the foliage will not hurt them; but it must be done early in the day, sufficient moisture being generally maintained by damping the paths and other places.

The Kitchen Garden.

Lettuce in frames will need careful treatment now, and though the plants enjoy plenty of air during bright weather, cold draughts must be avoided. Sulphur should be used on the under sides of the leaves when there is a tendency to mildew. Keep the soil lightly moved between the plants as often as necessary.

Asparagus.—Three year old crowns may now be lifted for forcing purposes. Too much heat must be avoided at the commencement, or the partially-rested crowns will only throw up very weak shoots. Batches should be introduced into the forcing-frames every two or three weeks, according to the demand.

Seakale.—As soon as the leaves have all died off, the crowns should be lifted and trimmed, reserving the strongest of the thongs for next year's planting. Store the crowns that are fit for forcing where they are easily got at as required. A week or two should elapse before placing any in heat, after which it should become a weekly operation.

Fruits Under Glass.

Vines for Early Forcing should now be in a fit condition for pruning, after which the annual cleaning should take place. This must not be done in a haphazard manner, but everything possible should be done that is conducive to cleanliness. Woodwork, glass, walls, pipes and trenches should all have a thorough washing down, the walls being relined and the pipes painted. The Vines themselves must also be thoroughly cleaned, and have a dressing with an insecticide, this being even more carefully done where they may have been infested with any kind of insect pest. After cleaning, the borders should receive whatever attention they may require in the way of renovation or top-dressing. This is an important factor in the ultimate success, as in most early vineries the borders are all inside and fairly shallow.

THOMAS STEVENSON.

(Head-gardener to E. Mocatta, Esq.)

Woburn Place Gardens, Addlestone, Surrey.

FOR NORTHERN GARDENS.

The Flower Garden.

Planting Lily of the Valley.—When allowed to get very thick in the beds, the flower-spikes become very small. Wherever it is necessary to replant, the present is a suitable time for the operation. Trench the ground deeply, working in a good deal of well-rotted farmyard manure, and, if the soil is inclined to be heavy, incorporate some sand with it. For convenience in picking the flowers, beds 4 feet wide are very suitable. Select the strongest available crowns and plant them about six inches apart, so that the base of the crowns will just be under the surface.

Planting Herbaceous Flowers.—The border being in readiness, planting is the next step. It is more effective to plant in clumps of not less than three, than to plant single specimens.

The Rock Garden.

Planting.—Generally speaking, associate the taller subjects with the bigger stones, find out the moisture-loving plants, and plant them at the base, placing suitable subjects higher up. Find out the requirements of the various subjects as to soil, and fill up the pockets they are to occupy accordingly. Aspect must also be studied, and one should keep in mind that, speaking broadly, the gems are the most exacting in their requirements.

The Rose Garden.

Planting.—We have now entered upon the ideal month for Rose planting, and those who intend planting should not defer the operation too long. Prior to being planted, the roots of the plants should be gone over, and all damaged roots be cut back to healthy wood with a sharp knife. Long, bare roots should also be well shortened; it is the fibrous roots which are

essential to the well-being of the plant. See that the bottom of the pit is either convex or flat; never leave the bottom concave. When adjusting the plant, see that it is at least as deep, or very slightly deeper, in the soil as it was previously. Firm the soil well right up to the base of the stem. A mulching of light, open material will facilitate the rooting process, and will ward off severe frosts from the roots. See that the plants, clumps or beds are correctly named, for even peers of the realm sometimes suffer from loss of "face memory."

Plants Under Glass.

Poinsettias.—Few plants brighten up a house during the dull days more than these showy plants. A temperature of 60° or a little over by night suits them very well. They last long in a cut state, but when so used they should be placed in a somewhat cooler house for a week or ten days prior to being cut.

Moschosma riparium.—This member of the Sage family, although not particularly showy, is very useful as a winter-flowering plant. See that the plants are not neglected for the want of water, or they will lose their foliage quickly. Continue to give them bi-weekly supplies of liquid manure. Do not crowd the plants.

Calceolarias.—As these plants are in active growth during the winter months, attention must be given to repotting; 3-inch, 5-inch and 7-inch pots are the usual shifts. They will generally require shifting into 5-inch pots about this time. Fibrous loam should form one-half of the compost; the other half should be mostly good Beech or Oak leaf-mould, with a little dry cow-manure and sharp sand. Vaporise on the first appearance of aphids. Keep the plants cool.

Fruits Under Glass.

Early Vinery.—Where ripe Grapes are expected in the beginning of May, a start should now be made. Shut up the house and commence with a night temperature of from 45° to 50°, with a rise of 5° during the day.

Figs.—As soon as Figs in pots become defoliated, they should be examined, and, if necessary, be repotted; if not, some of the surface soil should be loosened and removed by the aid of a pointed stick, after which the plants should be top-dressed with good loam and bone-meal or dry cow-manure. The plants can then be accommodated in a Peach-house or even in a shed, where they should be kept rather dry at the root, but not be allowed to become dust-dry.

The Hardy Fruit Garden.

Purchasing Gooseberries and Currants.—

Those who intend planting Gooseberries or Currants should lose no time in purchasing. It may not be amiss here to indicate a few reliable varieties for the benefit of the uninitiated. Taking Gooseberries first, *Langley Gage*, *White Champagne* and *Whitesmith* are reliable white varieties. Among yellows, *Early Sulphur*, *Golden Lion* and *Yellow Warrington* can be recommended. *Green Gascoigne* and *Langley Green* are two good green varieties; and two good reds are to be found in *Red Champagne* and *Wonderful*. *Whimham's Industry*, being an extra heavy cropper, is the general favourite for picking green for tarts. *Fertility* and *Red Grape* are two good varieties of Red Currant, and *Versaillese White* is a good White. Three good Black Currants are *Boskoop Giant*, *Victoria*, and *Black Naples*; but make sure that they are free from big-bud or the mite.

The Vegetable Garden.

Seakale.—The foliage having died down, it should be cleared away, the ground cleared of weeds, and, if available, a dressing of seaweed be given to the crop. A portion of the crop intended for forcing should be lifted and planted in rather light soil in a packing-case or bed where it can be covered over to exclude the light. Keep rather on the dry side, with a temperature of about 50°.

Swedes.—These should now be lifted and pitted or stored in a cool cellar among sand.

Protecting Celery.—Sharp frosts may occur now at any time, and Celery, if not protected, is sure to suffer. I find nothing better for the purpose than Wheat straw laid on lengthwise, and moved down to the base of the trench when the frost yields.

CHARLES COMFORT.

SEASONABLE NOTES ON CHRYSANTHEMUMS.

HINTS FOR EXHIBITORS.

DURING the first part of November the principal shows will be held in the Midland and Southern Counties. Further North, the other important exhibitions will follow closely, so that in the course of about three weeks dozens of magnificent displays will gladden the eyes of thousands of the general public and cause much joy in the hearts of enthusiastic growers. The latter include a big percentage of amateur cultivators, who have, in late years, grown some remarkably fine flowers. One amateur, who lives close to the writer, is now flowering his second collection of plants. He has only given his attention to them for three years altogether, and I have never seen any plants grown by a professional that bore finer blooms, nor specimens that were cleaner or healthier. He is a very intelligent cultivator, loves his plants, and spares no trouble in order to get them as perfect as possible.

No doubt there will be many readers of *THE GARDEN* who are showing for the first time this autumn. If they are content to enter in a few classes only, and so make them as strong as possible, they will be more successful than if they weakened the collections of blooms by entering many classes and being obliged to fill them. Very popular classes are those providing for six cut blooms on long stems, to be staged in vases, six of a yellow or a like number of a white variety being specified. Owing to the number of one variety being six, few growers are able to stage that number, so that an amateur will have a good chance of securing a prize if he stages nice blooms, even in size, fresh, and of rich colour. The most telling varieties for vases are yellow, white, rich crimson, yellow and bronze, and pink and white. Dull chestnuts, faded reddish bronze and badly-coloured specimens of amaranth and purple should not be staged unless in every case blooms of these are available at their best. Single-flowered varieties seem very easy to stage in vases, and they are more adaptable than the heavy blooms of the Japanese section; but the cultivator should avoid placing them so that they look straggly. On the other hand, spread out the flowers just enough to show off each one to the very best advantage. Take wedge-shaped blocks of wood to the show, so that trained specimen plants can be tilted forward a little; then both judges and public have a better view of them. Two blocks to each pot are required.

There is a tendency of late to build up groups of Chrysanthemums on tall erections such as draumpipes, tripods, even boxes, and big flower-pots. The inside portion of such groups, when closely examined, looks very ugly. Amateur exhibitors should do their best to be original, and stage low groups; they are much more effective than the tall ones, when the full beauty of the highest and back blooms cannot be examined.

Groups of Single-Flowered Varieties look quite charming when neatly arranged. It is only during very recent years that classes have been provided for this section in generous numbers. The first groups the writer saw were entirely spoiled through overcrowding. They contained lovely plants, a single specimen of which would have had a better appearance than the whole group. The flowers in the groups were simply crushed together. This

autumn exhibitors should avoid overcrowding, and employ only their very best plants. Never mind about producing a formal group, nice and even from centre to edge; have lightness of arrangement and harmony of colour with a neat finish; then a success will be scored. AVON.

THE FRUIT GARDEN.

RENOVATING OLD VINES.

[In Answer to a Correspondent.]

AS this is the season of the year for dealing with the roots and borders of Vines which are in a poor condition of health, whether the Vines be young or old, and as the information how best to deal with such Vines would be likely to be useful to many readers, I propose, with the Editor's permission, to go into the subject in greater detail than would be possible in reply to a question.

I am a firm believer in the strong recuperative powers of old Vines when given a chance by generous treatment in the way of pruning their roots and replanting in the best possible Vine soil, coupled with rest in spring and light cropping the first year afterwards. There are many Vine-growers, amateurs especially, who consider no labour too great, and will spare no pains in affording all possible help to their Vines in the way of attending to their foliage and fruit, and in ventilating, watering, &c., but who practically forget the existence of roots, or the want of them, and then wonder how it is that their Vines so often fail to produce satisfactory crops. It is not necessary to lay stress on or to emphasise the fact that success in Grape-growing depends in the first place on the quantity, health and strength of the roots of the Vines. Without such roots it is quite impossible to produce satisfactory crops, and the cause of failure in certainly seven cases out of ten will be found to be due to this cause. A successful Grape-grower ought to know, and does know, as much, or more, about the condition of the roots of his Vines than he does about the Vines themselves.

Your correspondent's Vines are old, and he finds out that the roots are deeply buried (a matter of about three feet, he thinks), and this has been done by annual top-dressings over a series of years without taking little or any of the old top-dressings off before adding the new. A gardener friend advises him to root out the old Vines and plant new ones. There are certain objections to this, and I do not think it is necessary. One is that the owner is only tenant for life. Other reasons are the extra expense entailed and the loss of a full crop for at least three or four years; moreover, there is a certain loss of quality in the flavour of the Grapes, as it is well known that old Vines produce Grapes of much richer quality and flavour than do young ones, and this counts for much with those who value quality of flavour more than mere size of bunch and berry.

The treatment I recommend your correspondent to adopt is the following, and I am confident he will not regret doing so provided the work is well and carefully carried out. Before anything is done to the border, let the new Vine compost in which the roots are to be replanted be got ready, so that there will be no undue exposure of the roots while the work is in progress. This compost should consist of the following items, and there should be as much of it prepared as will give a dressing over all the roots to the depth of

6 inches, not including that under the roots. The size of the border to dress will determine the quantity of soil required. To one cartload of turfy loam from an old pasture field (cutting off the grass as close as possible—the turves should not be cut deeper than 4 inches) add two barrow-loads of old brick ends broken to the size of hens' eggs. Add the same quantity of old mortar rubble, broken in the same way, also a bushel of quarter-inch bones, half a bushel of bone-meal, one bushel of lime and half a bushel of soot. Mix up well together, and lay by in a heap in a dry place ready for the time when it is wanted. The chief essential necessary in such a compost is the provision of conditions favourable for the formation of abundance of new roots—not so much rich soil for nourishing the roots. This can be added afterwards in the way of liquid manures.

Treatment of the Border.—Clear away all the surface soil of the border (no matter how much of it there may be) until a good body of roots is come to. Expose all these to within, say, 4 feet of the stems of the Vines. Examine every root. All those which are found diseased or cankered should be cut back to a healthy part. All long and fibreless roots should be shortened to within 5 feet of the base of the Vine stem, and all the tip ends of the smaller roots also should be cut back. Clear away the old soil from under these roots to the foundation and drainage of the border. This latter must be efficient, and probably is. If the subsoil is gravel or some other open material through which water passes freely, no concrete or other material is wanted for the bottom of the border. Put down a layer of the roughest parts of the compost under the roots with some small on top, and bed the roots (after they have been pruned) in the compost, adding more until the roots have been buried 5 inches deep. Tread the compost down firmly. The surface of the border from top to bottom should have a fall of 4 inches.

I mentioned in the foregoing that the roots of the Vines should not be disturbed within 4 feet of the stem of the Vines; but that is not to say that the old top soil down to a body of roots should not be removed. It should be, and a layer of the new compost laid over these roots to the depth of 5 inches; but the roots themselves in this part should not be disturbed. In your correspondent's case the roots are practically all inside, and he need not trouble about the recently added outside border this year; but in a couple of years' time it will pay him to serve this in the same way.

As soon as the top-dressing is finished, the border should have a good watering with clear water to settle the soil over the Vine roots. The border should at the same time be covered over with fresh leaves to the depth of 6 inches. Clean, dry straw will do it leaves are not available. Let this remain on until the end of April, when it should be removed and a mulching of short, well-decayed manure substituted for it. The border should also at this time have its first soaking of water. Towards June he will find the new soil will be filling with young roots. These may then be fed with liquid manure, applied once a fortnight or three weeks, according to whether the weather is dry or the reverse.

A Word as to the Treatment of the Vines.—Do not force them into growth in spring, but let growth come on slowly and in a natural way, without any artificial heat to speak of in the daytime, but a little must be provided at night. Let the Vines carry a light crop for the first year. They will carry a full crop the second year. O. T.

NURSERY NOTES.

MESSRS. W. SEABROOK AND SONS.

IT was a great pleasure for us to visit the nurseries of Messrs. W. Seabrook and Sons at Chelmsford on a gloriously sunny day early in October, after a lapse of some fourteen years. Naturally, we were prepared to see some changes, but hardly anticipated the wonderful strides that the firm has made during that time. The nurseries as we used to know them comprised about twenty acres; but so rapid has been the increase of business that now well-nigh a hundred acres are needed to meet the demands of the firm's customers, and several other large fields of good virgin soil are earmarked for future developments that are certain to accrue so long as the business is conducted on the same up-to-date lines that now prevail.

The senior partner of the firm, Mr. W. Seabrook, who is well over sixty years of age, has devoted a strenuous life to the study of fruit-growing and the raising of fruit trees, and was one of the pioneers of the cordon system, planting large plots with this class of tree before other market-growers had scarcely heard of them. Bush trees on dwarfing stocks, too, he long ago saw the possibilities of, but he also realised that to secure the best results from them, and to induce them to crop at an early age, particularly such varieties of Apples as Cox's Orange Pippin and Blenheim Orange, more than usual care was necessary in the selection of the stocks on which they were budded or grafted. With this end in view he started experimenting, and the result is that nowhere hardly in the country is Cox's Orange Pippin grown better than it is here. At the Boreham nurseries, some three miles out of Chelmsford and alongside the ancient Roman road from London to Colchester, both market fruit and young fruit trees for stocking orchards and gardens are grown, so that the would-be purchaser can see how the young trees thrive and crop on the stocks which the firm uses, and which have been selected as a result of many years' experience. In one field we were particularly interested in some ten acres of five-year-old bush trees of Cox's Orange Pippin. Every tree was carrying a really wonderful crop of fruit, in some instances as much as half a bushel, and when we remember that the market value of these is just now about £1 a bushel, the value of trees on the proper stock will be patent to all. Every other kind of Apple, Pear and Plum for which there is a demand is worked on stocks that have been found most suitable, hence customers may rely on getting trees from this source that will do well when planted, and give quick and bounteous returns in the way of fruit. To give readers some idea of the demand that there is for these trees, we may mention that we saw no fewer than 250,000 Apple stocks that had been either budded or grafted this year, and these will be trained into cordons, espaliers, bush, pyramid, standard or half-standard trees, according to their suitability and the demand that arises for them. Planted in long rows of ample width, it is a comparatively easy matter to keep the soil well tilled with horse-drawn implements, and scarcely a weed could be found among any of the nursery stock. What was of even greater moment to prospective purchasers, however, was the entire absence of disease and American blight. We were careful to keep a sharp look-out for serious pests of this kind, but they were not to be found.

In another large field we were particularly interested in some twenty thousand Black Currant bushes that have been planted out as a permanent crop. As most of our readers are aware, the curse of Black Currants in late years has been the big-bud mite, a pest that has caused many thousands of pounds' worth of damage to fruit plantations in all parts of the country. The variety which Messrs. Seabrook have planted so extensively is named Seabrook's Black. Although cultivated by the firm for market purposes for at least thirty years, bushes have not, previous to this year, been offered for sale. During the whole of that thirty years Messrs. Seabrook had never known it to be attacked by big-bud mite, possibly due, they thought, to the fact that they had not grown any other variety attacked by the pest near it. However, seven years ago it was suggested to them that it might prove immune, and to test it the firm arranged for a good number of bushes to be planted in another grower's field, between mite-infested bushes and in the very soil whence Baldwin's, badly attacked by the pest, had been grubbed. Each year a report has been made, and each year it has been to the effect that Seabrook's Black is quite free of the pest. Certainly there was not a trace of it when we saw the bushes and nursery stock, and as it is a vigorous grower, free cropper and of good quality, it should prove of great value to amateurs, professional gardeners and market-growers alike.

In addition to all kinds of fruit trees, the firm has, in recent years, taken up the raising of Roses, and this branch of the business is increasing as rapidly as the fruit tree section. At the time of our visit we noticed good healthy stocks of all the best bush, Polyantha, standard, weeping standard and Rambler varieties, and, were space at our disposal, much might be said about these. We left the nurseries, after a most enjoyable and interesting day, convinced that those of our readers who require fruit trees or Roses can with every confidence place their orders with this business-like and up-to-date firm.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—*The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.*

FLOWER GARDEN.

ROMNEYA AND CARNATION (J. C. H.).—In your locality you might lift and divide the Romneya at once, detaching any of the long or extending roots, and cutting them into sections an inch or more long, start them to grow in the greenhouse. If the soil of your Carnation border is infested by eelworm, it is highly probable that the plants also are infested, in which case new stock would be required. Had you sent us some of the failing plants, we could have decided the point for you. Are you sure the soil is free of wireworm—the worst of all soil pests to the Carnation? Apterite and Soilfume are two of the soil fumigants that may be applied according to instructions. These destroy many of the pests common to garden soils. In your case the addition of lime or lias

clay to the border would be of the utmost value, since the Carnation is not usually a permanent success in very sandy soils.

HARDY BORDER CHRYSANTHEMUMS (E. L. C. F.).—The cultural details required for the above are simple enough, and, as a rule, a bed of moderately rich loamy soil deeply worked and manured suffices. In many districts the plants perish in winter-time, not because lacking hardiness generally, but because they are kept soft and evergreen and in a growing state far into the winter months, when they should be resting. In these circumstances it is best to root cuttings afresh, February and March being a good time, planting them out in April or early May. For this purpose lift a plant of each variety in November, and protect in a frame till required. When the fresh young shoots are about two inches long, these may be used as cuttings. The following are useful and free-flowering: Carrie and Horace Martin, yellow; Crimson Polly and Goacher's Crimson, crimson; Crimson Marie Massé, bronze crimson; Nina Blick, reddish bronze; Calcedonia and White Massé, whites; Perle Rose; Improved Massé, rose lilac; Hector, mauve and pink; Flora, yellow; Mme. E. Lefort, orange; and La Luxembourg, bronze. The last three named are free-flowering Pompons, and these are usually of the hardest class.

SLUG-PROOF PLANTS (R. O.).—By your request for herbaceous plants quite immune from the attacks of slugs you have set us rather a formidable task. It is true that this pest may have a special fondness for certain groups of plants, but with a garden free of these it is more than likely that attention might be directed to other plants previously ignored. You appear to realise that the adjacent hedges are infested by the pest, though you are adopting no measure to trap him there. We think, however, were you to lay down slates, boards, or damp sacks near the hedges and examine them twice a week, you would get some surprising hauls. Or you might heavily dust the base of the hedgerows with lime or treat it with Vaporite, and, having by these means rid your garden of the pest, set out to enjoy not what the slugs rejected, but all the best a garden should contain. In the meantime you might experiment by trying such things as Hepaticas, Christmas Roses, a large number of Flag Irises, Potentillas, the rather important race of white Marguerites, Chrysanthemum maximum and varieties, herbaceous Phloxes, Pentstemon barbatus, Oriental and other Poppies, Aconitums, Heleniums generally, Helianthus or Sunflower, Achillea Ptarmica and its varieties, Lenten Roses, Anemone Dropmore variety, Columbine and Michaelmas Daisies. The young shoots of such plants as Campanula, Delphinium, Pyrethrum and all the Pink tribe are greedily devoured by the slug, while not infrequently the flowers of many plants whose leaves are unattacked are cleared off wholesale. Hence it would appear that in a land of plenty, only the choicest morsels are selected, though with any signs of scarceness it takes what it can get. Plants containing poison, or others whose juices are of a decidedly acid nature, may be objected to for these reasons.

HERBACEOUS PLANTS FOR TOWN GARDEN (In-terested).—There is such a wealth of subjects flowering in July and August that we think quite the best thing for you to do would be to purchase "The Hardy Flower Book," by E. H. Jenkins, to be had, post free, from our Publishing Department, for 2s. 10d. This invaluable book gives rather complete lists of all the best herbaceous plants, together with their height, colour, time of flowering and other things, with much other information of supreme importance to those who garden chiefly in the open air. To have a border effective over a long period, plantings of Irises to flower in May, June and July should be made, to be followed by Pyrethrum, single and double in variety, hybrid Columbines, Achilleas, a good selection of Delphiniums, Gaillardias, Pæonies, Oriental Poppies in variety, Heucheras of sorts, Monarda, Lychnis chalcedonica, and such like. For July and August the best things would be herbaceous Phloxes, Sunflowers, Campanula carpatia in half-a-dozen sorts, Scabiosa caucasica, Eryngium, Echinops, Red-hot Pokers, Aster Amellus in variety, A. ericoides, and a good set of Michaelmas Daisies. Such good and useful Lilies as umbellatum, croceum, excelsum, candidum, and the forms of speciosum should also find place, also Montbretias, which are so effective and graceful when in flower. For borders 6 feet wide it would be a good plan to arrange the plants in groups, say, not less than three plants to a group, three lines of groups alternately disposed being sufficient for the width named. The list of flowering shrubs to which you refer is of a somewhat mixed character, some plants being quite unsuitable to the border. If, however, you send us particulars of the width and length of the border, we will give you a suitable list of shrubs for it. With suitable shrubs might be associated Lilies, Irises, Daffodils and other plants to flower at varying seasons of the year.

THE GREENHOUSE.

TREATMENT OF DRACÆNA AUSTRALIS (Old Reader).—Your plant of Dracæna australis, whose correct name, by the way, is Cordyline australis, is not likely to survive the winter in the open ground. By far the better way will be to winter it in a cool room where it is safe from frost.

FERN FRONDS DISFIGURED (Old Reader).—There are both thrips and scale on the Fern fronds sent. Thrips can be readily kept under by vaporising with one of the nicotine compounds, but for the scale the fronds must be sponged with a solution of soft soap and water, at the same time loosening the largest of the scales with a pointed stick. In carrying this out, care must be taken not to injure the fronds.

EDITORIAL NOTICES.

Every department of horticulture is represented in **THE GARDEN**, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in **THE GARDEN** will alone be recognised as acceptance.

Office: 20, Tavistock Street, Covent Garden, W.C.

NOTES OF THE WEEK.

To Our Readers.—It is with pleasure that we are able to announce that Mr. George Dillstone, the talented landscape gardener on the staff of Messrs. R. Wallace and Co., has kindly consented to write us a series of articles on the construction of rock gardens. These will be illustrated by sketch plans of rock gardens actually constructed under Mr. Dillstone's supervision, and photographs showing the work when completed. To those interested in rock gardens these articles will prove of more than usual interest, and we trust our readers will make them as widely known as possible. We hope to publish the first in our next issue.

Preparation for Spring Bedding.—Although in some places the summer bedding is still looking little the worse for wear, such beds or borders should now be cleared if it is intended to fill them with spring bedding plants. It is important that Wallflowers, Forget-me-nots, Alyssums, Primulas and similar plants should be put out before the ground gets cold, so that they may become established, as it greatly assists them to stand the winter.

Bananas Fruiting at Kew.—When at Kew Gardens most visitors make a point of seeing the Bananas growing in the great Palm House. These are of more than usual interest at present, as three of the plants are maturing large bunches of fruits and two other plants are in flower. The largest bunches are forms or varieties of *Musa sapientum*, Gros Michel and Lacatan. Growing to about thirty feet high, the foliage of the Bananas is always an imposing feature of the Palm House.

Cutting Winter Cherry for Decoration.—Where the Winter Cherry, or *Physalis*, is grown for winter decoration for vases, it should now be cut, if this has not already been done, as the bladders will commence to perish if left out in the open much longer. Cut the shoots, tie them in small bunches, and hang them in a dry place, where the leaves which are now ripe will soon drop off, leaving the stems of bright-coloured bladders, which are so valuable either alone or mixed with other dried flowers.

A Beautiful Greenhouse Plant.—A plant that has recently come to the front, although by no means new, is *Lindenbergia grandiflora*. It is a most valuable plant for the greenhouse with its bright yellow, Musk-shaped flowers, which are borne in profusion, and last in bloom for about three months. A well-grown batch of this desirable plant, mixed with the beautiful *Salvia azurea*, is one of the chief features of the conservatory at the Botanic Gardens, Cambridge, at the present time, where it is greatly admired. It is of easy cultivation under greenhouse treatment, but requires a little shade during the summer. The sprays last for a considerable time when cut and placed in water, but the colour does not show up to advantage under artificial light.

Blue Salvias Flowering Late.—These plants have been a great success in the garden this year. The season has evidently been such as to induce healthy growth of medium strength; the plants are, in most instances, dwarf and very freely flowered. In several gardens we have lately noticed grand displays of blossom, and it seemed a pity to disturb the plants, yet it was becoming necessary work, as nearly all the other kinds of bedding-out subjects had lost their freshness, and all must give place to the spring-flowering ones.

Autumn-Flowering Bulbs.—Few plants are more valuable than the *Sternbergias*. Whether it is in the rockery, borders, or on the edge of shrubberies, they brighten it up with their beautiful yellow, Crocus-like flowers at this season. *Sternbergia lutea* and its variety *angustifolia* are two of the best, being very free-flowering and soon establishing themselves; but *S. macrantha*, with its larger flowers, which are a beautiful golden yellow, should on no account be left out. Most of the *Sternbergias* are very suitable for conservatory decoration when grown in deep pans or pots.

Mr. Hugh Dickson.—On the next page we have pleasure in publishing a portrait of Mr. Hugh Dickson, president of the National Sweet Pea Society for 1913-14. Mr. Dickson is a member of the firm of Messrs. Alexander Dickson and Sons of Newtownards, managing with considerable skill their seed and bulb business at Belfast. He is one of the best-known men in the horticultural trade, and his quiet, unobtrusive manner has endeared him to all who have had the pleasure of meeting him. The National Sweet Pea Society is to be congratulated on its selection of Mr. Dickson as president.

Strawberries in November.—We were much interested a few days ago when visiting a Dulwich garden to observe a bed of Strawberries still carrying a presentable crop of ripening fruits. The variety was St. Antoine de Padoue, one of the best of the hybrid autumnal Strawberries. The flower-buds had been removed from the plants until early in September, when the fruits were allowed to mature. The berries are globular and of bright red colour, while the plants are as vigorous as the summer-fruited varieties. The bed in question is in a sheltered spot on a warm border, and the plants each autumn bear freely until the frosts set in.

Storing Lobelias for the Winter.—*Lobelia fulgens*, *L. cardinalis* and others of that type cannot always be relied upon to stand the winter outside. They should now be lifted, placed in boxes in sandy soil, and stored in a fairly dry place, not necessarily a greenhouse, but a certain amount of light is preferable to a dark shed. Although it is important that they should be kept from excessive wet, it is also important that they should not be allowed to get too dry. They can be easily increased by dividing the plants in the spring, or seed sown now will make better plants for putting out next summer than those raised from seed next spring.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Prizes for Front Gardens.—The village in which I live is not at all beautiful, and most of the gardens are neglected or unattractive. By way of encouraging the inhabitants to interest themselves in beautifying the village, I think of offering three prizes for the gardens and house fronts which are kept most satisfactorily all the year round. Some of your contributors must have sympathy with, and practical experience in, such a scheme, and I shall be most grateful if I may be allowed to benefit by that sympathy and experience in the framing of rules which will give all the competitors a fair chance.—
MARGUERITE.

Is the Almond Hardy in Scotland?—At a meeting of the Scottish Horticultural Association, held some months ago, when the merits of ornamental trees and shrubs suited for villa gardens were being discussed, several members testified that the Almond is not hardy in the neighbourhood of Edinburgh. As the Almond is such a desirable subject, both on account of its beauty and its early flowering, it would be interesting and instructive if readers of THE GARDEN North of the Tweed who have grown, or attempted to grow, it would give their fellow-readers the benefit of their experience, indicating the district where such experience has been gained.—
CALEDONIA.

Gentiana verna Flowering Late.—I have been much interested by Mr. Malby's notes on *Gentiana verna* in last week's issue, page 548. I should be glad to hear from him or any of your readers whether it is common for this plant to bloom twice in the year. During September and October of this year I have had eight flowers on a small patch of the *Gentian*, which bloomed fairly freely in the spring, and there is a flower just opening on a plant which I bought as *G. angulosa*, though I can detect little or no difference between it and *G. verna*. One regards this *Gentian* as so essentially a spring-flowering plant that it is surprising to find it in bloom so late in the year. *G. verna* is growing in sandy loam in a rather shady, moist place, while *G. angulosa* is in sandstone moraine fully open to the sun.—A. E. BACKHOUSE, *Darlington*.

Alpines Flowering in October.—Reading your list of alpine and rocky plants in bloom on October 1 in your issue for October 18, page 525, tempts me to send you a list of plants from a small garden 200 feet by 30 feet in the North-West, all in the open: *Alyssum sinuatum*, yellow; *Antirrhinum gibraltarium*, reddish; *Arabis alba flore pleno*, white; *Astrantia gracilis*, white; *Borago laxiflora*, pale blue; *Campanula Burghaltii*, blue-white; *C. carpatica*, blue; *C. garganica*, pale blue; *C. glomerata* hybrid, deep blue; *C. muralis*, blue; *C. rotundifolia*, blue and white; *Cardamine rotundifolia*, white; *Chrysogonum virginianum*, yellow; *Cimicifuga simplex*, white; *Corydalis lutea alba*, whitish yellow; *Colchicum*, *Crocuses*, *Cyclamen*; *Dianthus*, various; *Erica Serlei*, white; *E. stricta*, pink; *E. vagans*, white; *Erigeron glauca*, lavender; *Erodium Manescavi*, red-mauve; *Erysimum pulchellum*, yellow; *Geranium Endressii*, pink; *G. sanguineum*, red; *G. striatum*, pink veined; *Geum rivale* Leonard's variety, red; *G. r. Orange*, *Gypsophila Steveni*, white;

Helianthemum (various), pink-yellow; *Hypericum olympicum* and *H. empetrifolium*, yellow; *Linaria acutiriloba*, purple; *L. alpina rosea*, rosy; *L. anticaria*, white and yellow; *L. pilosa*, purple; *Linum*, blue; *Lysimachia Henryi*, yellow; *Menziesia polifolia*, rosy white; *Nepeta Mussinii* (two forms), lavender and bluish; *Origanum hybridum*, pinkish; *Oxalis floribunda*, pink; *O. f. alba*, white; *Potentilla alpina*, white; *P. hopwoodiana*, *P. Miss Willmott*, *P. minima*; *Perowskia atriplexifolia*, lavender; *Plumbago Larpentæ*, slaty blue; *Polygala Chamæbuxus purpurea*; *Polygonum affine*, reddish; *Santolina Chamæcyparissus*, yellow; *S. pinnata*, creamy white; *Saxifraga Fortunei*, white; *Scabiosa percephala*, pale lavender; *Sedum calabricum*, pinkish; *S. Ewersii*, pinkish; *S. pulchellum*, pinkish; *S. spectabile*, pink and deep forms;

MR. HUGH DICKSON, PRESIDENT OF THE NATIONAL SWEET PEA SOCIETY FOR 1913-14. (See previous page.)

Teucrium Chamædrys, reddish; *Tunica Saxifraga*, pink; *T. S. alba*; *Veronica corymbosa*, deep blue; *V. spicata alba*, *Vinca Double Blue*; *Violas Bowles' Black*, *Mrs. Bowles* and *bosniaca*; and *Zauschneria*, red. Of those mentioned I would specially draw your attention to the following: *Alyssum sinuatum*, yellow, which has been in bloom since June. *Astrantia gracilis*, white, similar to, but much finer than, *A. minor*. *Cardamine rotundifolia*, white, an old plant, but very fine in early spring. *Corydalis lutea*, the pale form, is in flower almost all the year round. *Plumbago Larpentæ*, blue. This plant is fine with the crimson foliage in autumn, grown in the warmest possible position. *Veronica corymbosa*, deep blue, so named by Mr. S. Arnott, is only 6 inches high, and a choice gem for late flowering. *Viola Mrs. Bowles*,

lavender blue, a most continuous flowerer. The flowers stand up well clear of the foliage. *Zauschneria*.—I have two forms. The early-blooming one is not so woolly as the other.—T. O. WALKER, *Carnforth*.

The Persian Cyclamen as a Biennial.—Mr. Blair's experience with two years old *Cyclamen* (see page 536, October 25 issue) differs in several respects so much from my experience, and I have no doubt also from that of other growers, that in fairness to those whose knowledge of the plant is slight, something should be put forward in favour of these. The treatment of second-year plants varies so considerably, and yet may result in each case in success, that one is forced to conclude that the treatment given by your correspondent has in some particulars been incorrect, the more so if the plants are "easily beaten" by young plants. Ours receive no special culture as regards soil and manure from that given to the usual run of soft-wooded plants, only being treated to a warm temperature while growing, and the difference is all in their favour. I have just measured a few of the largest specimens, which are each 2 feet 3 inches across, and from each I enclose a leaf for your inspection. The flowers are not yet out, but I expect them to be quite as large as those produced by the younger plants, one of which gave us last year's flowers up to 6 inches in diameter, and another, a ragged double, almost as large. I may add that *Cyclamens* succeed best here grown on as stove plants, in a low pit, along with table *Crotons* and *Dracænas*. In the autumn they are transferred to a cooler pit along with *Primulas* and *Geraniums* to flower. I differ only in these respects from Mr. Blair, and concur with him in advising the more general cultivation of these charming flowers, so very useful for cutting, and the plants for massing in the house.—R. P. BROTHERSTON, *Preston-kirk, N.B.*

—I quite agree with Mr. Blair that it is best to grow the *Cyclamen* as a biennial. We grow it here on that principle, with very good results, and never think of saving any old corms. We sow our seeds about the third week in July, placing them straight away in a cold frame. About the first week in September we place them in a temperature of 50°, and by the second week in October prick them off into 2-inch pots. We believe in pricking off early, as we find we get much larger plants. Of course, extra care is required in watering to keep the soil from becoming sour. We then place them in a temperature of 60°, keeping them close to the glass. In this position we keep them until about the first week in February, when they will be found to have filled their pots with roots and made about eight or nine leaves. We then pot them into 4-inch and 4½-inch pots, according to strength, keeping them still in a temperature of 60°. About the first week in June we pot them into 6-inch pots, placing them straight into a cold frame. They remain there until the first week in September; then we house them, as it is desirable for us to have a number of them in bloom by the first week in November. They continue to bloom until the end of April. What more does one want than to have them in bloom for six months? In February of this year we had one plant carrying seventy-one fully-expanded blooms, and still showing more buds. Some of the blooms had six and seven petals, and measured 6 inches from tip to tip. We had several plants with forty, fifty, sixty and sixty-five blooms; so who says it is impossible to have fine plants by this method? We have them now carrying fourteen to eighteen blooms.—F. C. WILLIF, *The Gardens, Great Walstead, Lindfield, Sussex*

Rose Peace.—I wonder if "G. G." (on page 534) is alluding to the Tea-scented variety? I assume he is, as I am not aware that there are two varieties of the same name. I find this an excellent Rose for outdoors, plants of dwarf growth flowering abundantly, with huge petals of a pale citron colour, which under glass would be paler in tint.—PAX

Mildew on Roses.—Many complaints have reached me this year as to the extent Roses have been attacked by mildew. Even whole localities have been vigorously infested, after much washing of the plants with sulphide of potassium had been done, with no effect of value. As a rule, in other years this chemical has been efficacious; this year in many gardens it has been quite useless. I have at last come across a distinctly effective remedy for this troublesome fungus, viz., Serum, prepared and sent out by Messrs. Gleeson and Co., Watford. Whatever it contains, it is wonderfully effective. Early in October many of my plants were badly attacked by mildew. I applied Serum as directed, 2oz to a gallon of cold soft water, well stirred, thoroughly drenching the plants. The result was marvellous. New leaves commenced to grow from the points of badly-infested shoots within two days, and the plants have continued quite free from fungus. Such a remedy is indeed a boon to Rose-growers.—E. M.

The War on Wasps.—In your issue of October 25, page 534, your correspondent Mr. Copeland seeks information from fellow-readers of THE GARDEN of their methods in catching queen wasps. My own method is to watch the Gooseberry bushes in the spring when they are in bloom, for, on the queens waking up from their winter's sleep, they seem attracted to the Gooseberry bloom to feed before commencing nest-building. If while walking past the bushes queens are seen, keep an eye on them till they settle on a bloom, when they may generally be knocked down and killed; or by pulling a piece of elastic tight and letting one end go with a slash at them it will often kill them while they are busy getting nectar from a flower. In this way, if the bushes are often looked at, great numbers may be killed where they are plentiful. Also in the autumn keep a sharp look-out in all kinds of buildings, outhouses, or even dwelling-houses, for the queens get in all sorts of places under cover for their winter's sleep.—S. K.

—In response to your invitation on page 534, issue October 25, I enclose the following, for the damage done to fruit by these pests, especially during a dry season like the past summer has been, certainly calls for some really well-organised plan of destruction. We have destroyed considerably over a hundred nests with cyanide in and around the garden here, and in many were quantities of young queens; but, notwithstanding that, great damage has been done. In reply to questions asked by Mr. Copeland, (1) I would suggest that in large fruit-growing areas the growers themselves combine and award a substantial prize for the greatest number of queen wasps sent in by a certain date (e.g., early in June); and in places where fruit is not grown on such a large scale, the local horticultural societies might adopt the same plan. The latter is already carried out in some places, and though only on a very moderate scale, the results must indeed be a gain in those particular districts. In gardens (private or otherwise) remuneration should be given for all queen wasps killed by members of the staff, for money so spent would unquestionably be well laid out. With the growing popularity in school gardening,

managers or local authorities could perhaps be persuaded to award prizes to the children for the greatest number of these pests caught. A case in which the children figured in this way came under the writer's notice some time ago. A horticultural society in Berkshire offered a small prize for the greatest number of queen wasps sent in by a certain date by any child in the district. The winner of the first prize had captured between five and six hundred, to say nothing of the other entrants! Such results as these surely speak for themselves. (2) As regards queen wasps entering bottles, very few indeed were caught here during the summer, either in bottles or other traps. The spring and autumn, of course, are the best times to capture queens, i.e., when they are searching for places or material for nesting, or when they are preparing to hibernate, such presumably being the case when so many were recently caught in a stokehole, for such places as potting-sheds and stokeholes are ideal for the purpose. (3) A good trap can be made by the use of two hand-lights, one resting on the other, the lower one raised from the ground on bricks and having holes in the lid to enable the wasps to pass through to the upper light (which must be hole-proof). To entice the pests to enter, portions of fruit are placed under the lower light, and more is put in the upper one, to which they will naturally ascend. To destroy the insects when a large number are captured, sulphur is placed below and set alight, the fumes rising and having the desired effect. Several such traps have been used here this summer, with great success.—H. TURNER, *Serby Gardens, Bawtry.*

A Good Spring Bed.—One of the most simple, and at the same time one of the most pleasing, spring beds which it has been my privilege to plant was composed of the following subjects: Golden Polyanthus were used to form a thick carpet, the plants being placed thickly so that the outer leaves completely covered the soil. Between the Polyanthus roots the scarlet Tulip *Artus* was used. The bulbs of this Tulip always come to hand in excellent condition, and it is an ideal variety for bedding purposes. The great thing in planting bulbs is to make sure that they are resting on the soil at the bottom of the hole, and also that they are planted at an even depth, thereby ensuring an even display of flowers. The Polyanthus can be raised from seed sown in pans in May, and afterwards transplanted in a shady position until the beds are ready. They may also be increased by division. A fresh stock from seed is, however, preferable in most cases.—COLIN RUSE, *Sulhamstead.*

FORTHCOMING EVENTS.

November 10.—United Horticultural Benefit and Provident Society's Meeting.

November 11.—Shows at Belfast (two days) and Birmingham (three days).

November 12.—East Anglian Horticultural Club's Meeting. Shows at Buxton, Gainsborough (two days), Faversham (two days) and Dulwich (two days).

November 13.—Shows at Nottingham (three days), Sheffield (three days), Romford, Newport (Monmouth), and Scottish Horticultural Association's Show (three days).

November 14.—Leeds Paxton Show (two days). Shows at Rochdale (two days), Huddersfield (two days) and Bradford (two days).

November 15.—Shows at Burton-on-Trent and Batley.

HOW TO TREAT GRASS BANKS.

IT is well within the memory of all who garden for pleasure that in their heyday grass banks formed a notable feature in garden design. These were usually introduced where a transition in level occurred, and were probably considered the most satisfactory method of dealing with an awkward situation. Many objections might be taken to these, but it will suffice for the present to mention their lack of interest and their difficulty of upkeep, which, even under the most favourable conditions, can never rival a level lawn of close-cut turf. With the present rage for hardy plants it must inevitably follow that the space usurped by grass banks will be coveted for something choicer, and in reviewing the various methods for beautifying such a position, the grass bank appears in its true light and is, after all, only a makeshift. Were such a bank placed at some distance from the house, as when it occurs as part of the boundary, a semi-wild treatment would undoubtedly appeal, and if massed with Rambler Roses of the wichuriana type and with some regard to the harmonious arrangement of the colours, such a bank would become an impressive feature and call for considerably less attention than the weekly ordeal of mowing grass. If the space is too restricted for Roses of this class, the bank may still be rendered more interesting by introducing hardy bulbs—Daffodils, Muscari Heavenly Blue, Anemone apennina, Chionodoxa, Scillas—and with Autumn Crocuses and Colchicums a moderately long season of flowers would result. The grass can be mown at least once in the interval between the flowering of the spring and autumn bulbs.

When banks arise close to the house, it is often more feasible to support them with walls, and so throw the ground into well-ordered terraces. A scheme of this character offers great inducement to the ardent horticulturist, for with the wall built in mortar, either with or without the accessory balustrade, opportunity is presented for clothing the same with the finest types of Roses, climbing plants and half-hardy shrubs. Such a wall will foster only subjects that we have difficulty in cultivating in the open, or whose beauty can only be seen to advantage when given the support and shelter of a wall. Walls of this character can also be profitably utilised by the addition of a narrow border at the foot whereon to plant subjects of doubtful hardiness, including Crinums, Watsonia, Romneya, Roscoea, Gerbera, Agapanthus mooreanus, Cushion Iris and Iris stylosa, Tricyrtis hirta and Antholyza.

It is frequently found desirable to afford a thorough change in the garden scheme, and in converting such a bank into a home for hardy subjects it is well to bear in mind the picturesque effect of a wall planned and planted on the dry-wall principle. Nearly any kind of stone answers this purpose. Soil is used as the binding material, and into the wall interstices alpine plants are introduced as the work proceeds, so that where the wall is built on principles that have the welfare of the plants at heart, a riot of alpine life and beauty bursts from the wall face and instinctively a feature of perennial interest is opened up, and the charm and beauty of the garden gain immeasurably by its presence.

THOMAS SMITH.

Coombe Court Gardens, Kingston-on-Thames.

TREES AND SHRUBS.

CLERODENDRON FÆTIDUM.

WHILE most of the members of the *Clerodendron* family require tropical or warm greenhouse treatment, there are three species, all natives of the Far East, which are fairly hardy in this country. These are *C. trichotomum* (the Kusagi of China and Japan), *C. Fargesii* (a native of China)

CLERODENDRON FÆTIDUM.

and the subject of this note, also from China. In the milder parts of the country *C. fœtidum* forms a shrub and flowers freely in the open. In the London district the stems are cut down to the ground during most winters, but this only seems to induce the plants to throw up more vigorous growths. These are often 3 feet to 4 feet in height, very sturdy, with large, deep green, glossy leaves and a terminal head of closely-packed blossoms 4 inches to 5 inches across. The colour of the flowers is bright rosy red. The name *fœtidum* is very misleading, for the flowers emit a pleasing fragrance, and it is only when the stems are cut or the leaves bruised that the unpleasant smell, denoted by the name, is perceptible. *C. Bungei* is a name by which the plant is sometimes known. Propagation is readily effected by pieces of the root. Last winter, when forking through the shrubbery border where the plants are growing, some of the roots were broken, and now the surrounding ground is freely sprinkled with young plants. The flowers of this shrub are often sent for naming, owing, no doubt, to the fact that the plant readily establishes itself and throws up many suckers from the roots. The fragrance of the flowers has been likened to that of Honeysuckle.

A RARE CHINESE HORNBEAM.

(CARPINUS POLYNEURA)

AMONG the numerous trees which exploration in China has brought to light during the last twenty-five years, few are more interesting to the arboriculturist than *Carpinus polyneura*. We are indebted to Mr. Augustine Henry for its introduction, he having sent home seeds from Central China in 1886. It is a rare tree, about thirty feet in height, growing on the mountains of Eastern Szechuan and Western Hupeh. Only one raised from this sending of seeds is now in cultivation at Kew. It is now about seventeen feet in height. The tree flowers and produces fruits almost every year, but until the autumn of 1912 no mature seeds were found. Among a quantity of seeds collected last autumn and sown in October as soon as ripe, several have germinated. Though there are no fruits on the tree this year, we may reasonably hope that as the specimen grows, having once produced seeds, the same thing may be expected again during a favourable season.

The Chinese Hornbeam is distinguished from other species of the genus by the comparatively small and smooth, flat leaves, the Hornbeams generally being distinguished by the plicate leaves. The leaves of *Carpinus polyneura* are not more than 2½ inches long by an inch wide, the only other species with as small or smaller leaves being *C. orientalis*, a native of South-Eastern Europe and Western Asia.

SPIRÆA AITCHISONII.

THIS is one of the best of the tall-growing shrubby Spiræas or Meadow-sweets. It is a native of Afghanistan, and grows about ten feet in height.

The plants make long, arching growths, which in summer are clothed with handsome pinnate leaves up to a foot in length. The flowering season is July and August, when the large bushes are a pleasing sight with the large terminal panicles, 1½ feet to 2 feet long, consisting of quantities of small, white flowers. This *Spiræa* makes a good lawn specimen, and is also very effective when massed in large beds or in the shrubbery border.

Seeds, which ripen freely on the bushes, form a ready means of propagation. The plants delight in a deep, loamy soil, with an annual mulching of old decayed manure. By annual pruning in February or March, the grower can, to a considerable extent, restrict the size or otherwise of the bushes. The growths made the previous year should be cut back to within 2 inches or 3 inches of the old wood, unless it is desired to increase the size of the bushes, when correspondingly longer growths must be left. Usually, each year one or two vigorous growths push up from the base; these should be merely topped, cutting out one or two of the old stems as they become exhausted from constant hard pruning.

A. O.

THE ROSE GARDEN.

ROSE-GROWING IN TOWN GARDENS.

IT is unnecessary to point out that, in Rose-growing, the town gardener is handicapped beyond his country cousin. He finds this out for himself with the first Crimson Rambler he buys. His season begins with the aphid and ends with the mildew, and all too frequently he lets it go at that. Now, aphid may be readily overcome, and even mildew yields to treatment; therefore, if he be a true enthusiast, he will rise superior to these difficulties, though, in order to do so, he may have to "stoop to conquer" in a rather too literal sense. The situation of his Rose beds is an all-important matter to the suburban grower. Roses delight in an abundance of air and sunshine, and, if his garden offers many places whence these can be obtained, he is exceptionally fortunate. In any case the best position for the beds will be towards the north-west corner of the garden, as far away from the house and walls or fences as space will permit. Here the plants will get the fullest benefit from the early morning sun, and will be sheltered from the north winds.

Soil is, of course, one of the first considerations. It is generally known that the best rooting medium for Roses is a heavy maiden loam, with a liberal admixture of decayed manure. This is the ideal; in actual practice most Roses have to put up with much less. In making up the beds, however, one must always bear in mind that the main requirements of the roots are free drainage, aeration and a constant supply of moisture. The first two are obtained by thoroughly trenching the ground, the last by adding clay where the soil is light. The town Rose-grower should import clay when necessary.

SPIRÆA AITCHISONII.

even before manure, yet few seem to trouble about doing so. Instead of spending all the money on his plants, it would pay the gardener much better, and give infinitely more satisfaction, if he were to lay out half of it in preparing the ground for them.

One of the most important elements of the soil is lime, and this is frequently deficient in town gardens. Roses require an ample supply of it, and, where necessary, it should be added when the beds are made up. For heavy soils slaked lime is best, and should be dug in at the rate of half a pound to the square yard. To light soils add pulverised chalk in the proportion of 2lb. to the square yard. Of course, where the subsoil is chalk, no addition of lime will be required. The earth with which the town gardener has to cope, often enough, consists of old worn-out soil, which previous occupants have thoughtfully enriched with cinder ashes. The only way to deal with this is to entirely remove the top spit, and after the remainder has been dug up and liberally dressed with horse or cow manure (according to whether it is heavy or light), fresh loam must be brought in to replace the soil that was taken away.

Thoroughly trenching, and manuring the ground is an actual necessity if Roses are to be grown successfully, and it is far better to make but one Rose bed properly than to have several which are only forked over. The manure used should always be in a well-rotted condition, and it must be free from shavings or other objectionable material. Horse manure from tarred roads should on no account be used, nor any manure to which disinfectants have been added.

Of artificial manures, bone-meal is one of the most useful. It should be applied, when the ground is trenched, at the rate of 1lb. to every three yards, and subsequently used as an autumn dressing combined with sulphate of potash. Take three parts of the bone-meal to one part of potash, sprinkle a small handful around each tree and tork in lightly. For early spring a good manure, and one which is lasting in its effects, is made up as follows: Superphosphate of lime, 12lb.; kainit, 10lb.; Epsom salts, 2lb.; sulphate of iron, 1lb.; and plaster of Paris, 8lb. Mix well together and apply a small handful to each square yard during February or March.

For summer feeding nothing is better than cow manure water, well diluted. Soot water is frequently recommended, but its manurial value is derived only from a small and varying percentage of sulphate of ammonia. Since the latter may be purchased very cheaply, and is cleaner and easier to handle, it is in every way to be preferred. Half an ounce to a gallon of water is a safe proportion, and used thus it is an invaluable stimulant for an exhibitor, as it adds materially to the size and colour of the blooms; but it should only be applied when plants are in bud, allowing an interval of a week or more between the applications. In feeding Roses it must be remembered that stimulants

should be used only on established plants that are growing freely, and that the ground should always be in a moist condition before the fertiliser is applied. Another important point is to vary the diet as much as possible, and apply it only in a weak solution. In my next article I will deal with the principal pests of the town Rose garden.

Thornton Heath

P. I. GODDARD

ROSES IN THE WILD GARDEN.

MUCH has been said and written in favour of what is termed "wild gardening." In some large private gardens a portion of the grounds, generally a considerable distance from the mansion or from the formal garden, is set aside for "natural" gardening. There are a large number of subjects suitable for this work, but none so effective as Roses when allowed to ramble at will. The common Dog Rose, with its shoots laden with flowers, also gives a colour effect with its hips in the autumn. There are many varieties of the wichuraiana and other types that may be used. Big clumps of one kind should be planted. *Rosa rugosa* is especially suitable where cover is wanted

AN INFORMAL BANK OF ROSE ALBERIC BARBIER.

for birds, as both pheasants and partridges are fond of the pulp of the fruit.

Of the early-flowering set we have Alberic Barbier, Pink Roamer, Jersey Beauty, Leuchtstern and Blush Rambler, to mention a few. Perhaps the Austrian Copper and Austrian Yellow are worthy of special mention, the colouring when in bold masses being charming. The Japanese Roses (*Rosa rugosa*) also give a variety of colour. The following are of vigorous growth: *Atropurpurea*, *alba*, *umbonata*, *rubra* and *repens alba*. The latter is of a more graceful habit. Pink *wichuraiana*, white *wichuraiana*, *wichuraiana rubra*, Crinon Rambler and Dorothy Perkins are a few that give a successive display.

In small gardens there are generally odd corners or a tree stump which Roses may be made to trail over. A few varieties that do well anywhere are Dundee Rambler, Virginia Rambler, Félicité Perpétue, Flora, Longworth Rambler and Thalia. For forming hedges or covering unsightly hedges nothing equals the Penzance Briars, of which there are several good varieties. The flowers are followed by large quantities of scarlet hips. A. J. H.

IN A HAMPSHIRE GARDEN.

SOME OF THE NEWER ROSES.

(Continued from page 549.)

Evelyn Dautesey (S. Motteley and Son, 1911).—A striking Rose of good habit and form; colour, soft salmon pink, and outer petals carnine rose with a deeper centre. After the style of the old Danmark, a sport from La France, but much deeper in colour and stronger in growth. Should make a good exhibition Rose. I remember seeing some very good specimens at Newport (Isle of Wight) Show this last season, exhibited by the Locksheath Nurseries. Their Rose manager thought a great deal of the Rose, and strongly recommended it to me. I have not grown it, but shall do so next season.

Frau Margrethe Moller (Poulsen, 1912).—Another Rose that I have not grown, but that I am told by more than one grower is going to be useful. Messrs. Frauk Cant had some fine flowers at the "National." Colour, a good deep pink, with a lighter edge to the petal, fragrant and a good grower. It was described as one of the best of the Continental Roses of 1912.

Ferniehurst (Alex. Dickson and Sons, Limited, 1911).—A beautiful Rose this when you can get it, but it has not been very free-flowering with me. Perhaps its very upright habit is against the free-flowering character. Colour, pale fawn, with a suggestion of pink. A good flower is very well finished, a model in its way, that has the appearance of being carved out of wax. Its foliage is very fine, large and leathery, and a good bronze green. The flower is slightly scented rather than strongly perfumed. The flowers are quite full size.

George Dickson (Alex. Dickson and Sons, 1912).—I have already referred to this Rose at some length in my general review. I only now mention it to say it is the finest exhibition Rose of its colour, and every exhibitor must have it unless he wishes to be severely handicapped.

George Reimers (Souper et Notting, 1910).—I am afraid after two years' trial this Rose must be said to be of no use for exhibition. It is a good red for the garden, but that is the most that can be said of it here. Further North, where it could grow more slowly, it might occasionally be useful.

Geoffrey Henslow (Alex. Dickson and Sons, Limited, 1912).—This is a very fine piece of colour, a much deeper shade than G. C. Wand, but of the same brilliancy, which is called orange crimson. The flowers are globular, imbricated and of good substance. A fine exhibition flower, a good grower, erect, fairly free-flowering and deliciously scented. Will be confused with the Hybrid Perpetual of the same name, but thus, the Hybrid Tea, is to be preferred of the two.

James Ferguson (Ferguson, 1911).—A silvery pink sport from Caroline Testout, with which it

is identical in every other respect. I have had some beautiful flowers of it from my two plants, and it is worth making a note of. It is probably the best of the many Caroline Testout sports.

Jonkheer J. L. Mock (Leenders, 1910).—A fine exhibition Rose, a very deep pink bicolor, of good shape and with a great deal of substance. A fine grower, frequently exhibited, with good, large flowers that are very fragrant. It has, I think, come to stay, and those who have not grown it should try it. In a list of twenty new Hybrid Teas that Mr. Mawley asked the leading growers and amateurs in the kingdom to place in order of merit last autumn for the purposes of his Rose Analysis, this Rose took the high place of fifth in the table, the trade placing it even higher, namely, third. It was very good with me last

in plenty. It is a robust rather than a vigorous grower, and produces one flower at the end of each shoot that grows very slowly. From its pertume one would judge there is a good deal of Tea blood, possibly *Maman Cochet*, in its veins. The wood is stiff enough to hold the flowers erect, and they do not require staking; but it would require protection in a wet season. Quite a reliable Rose for an exhibition, but useless for any other purpose.

Lady Greenall (Alex. Dickson and Sons, 1911).—One of the most beautiful Roses I know, but hardly large enough for the exhibition boxes, and I will refer to it under the garden Roses later.

La Galissiere (Schwartz, 1909).—A large, rather loosely-formed flower, a bicolor, bright silvery rose, reverse carmine. I have seen it

BORDERS OF HARDY FLOWERS IN A GLOUCESTERSHIRE GARDEN.

season (1912), and has, I think, been even better this.

King George V. (Hugh Dickson and Son, 1912).—A rather large flower, deep velvety plum colour, that is only at its best for a short period. Unlike most of these dark-coloured Roses, it opens freely, and I have seen some fine flowers of it; but, personally the colour is not one that appeals to me. A good grower and strongly scented.

Lady Barham (Alex. Dickson and Sons, 1911).—A Rose after the exhibitor's heart. He knows when he puts it in his box that it, at any rate, will stand. Very large flowers of globular shape; colour, flesh, dull rather than bright, an enormous number of petals packed so tightly that many of them can never see the light. It has been good this year. A very fine flower took the silver medal for the best Hybrid Tea for Messrs. Prior at Southampton. Weight and substance are here

exhibited lighter in shade than *J. L. Mock*, but it is a similar stamp of flower.

Leslie Holland (Hugh Dickson and Son, 1911).—A wonderful colour, very free-flowering, sweetly scented, but very little good for exhibition. Down here in Hampshire it opens too quickly to stand the strain of a journey in a box. In a cooler climate it would, no doubt, behave differently. Here I must call it only a garden Rose, but probably the very best of its colour, growth, habit and free-flowering being all prominently good. A cool season will probably suit it better, and it will then be exhibited for its colour, which is brilliant. It has been shown in wonderful form, with large flowers of great substance, by the raisers. Moreover, it has been awarded the gold medal of the National Rose Society.

Southampton. HERBERT E. MOLYNEUX.

(To be continued.)

THE FLOWER GARDEN.

FLOWER BORDERS AT AMPNEY PARK, CIRENCESTER.

I SHALL be very pleased if you think this photograph of my borders is suitable for **THE GARDEN**. They have been full of colour this summer and much admired. The hedge at the back is a mass of red Dahlias of different shades. The tall plants are Michaelmas Daisies of different sorts, with large groups of *Anemone japonica* (white), *Delphiniums* (some of which are flowering for the second time), *Spiræa Aruncus*, *Pæonies*, &c. We fill up spaces with annuals, and this year have large patches of *Pentstemon Southgate Gem*, *Coleopsis*, *Cosmea*, *Alonsoa*, *Browallia*, *Zinnia*, *Salvia Bluebeard*, *S. farinacea*, &c.

Cirencester. A CRIPPS.

THE CAMPANULAS OR BELLFLOWERS.

(Continued from page 551.)

C. latiloba.—See *C. grandis*.

C. Leutweini.—A foot high, and making a tuft of neat blue flowers in June. A Greek species, liking a rather dry soil.

C. Medium.—The well-known Canterbury Bell requires no mention further. With its calycanthema varieties it is one of our most valuable border biennials. Sow early to have good plants the following year.

C. michauxioides.—A handsome species, but practically biennial, and giving in July tall spikes of loosely-arranged, open, light blue flowers. Seeds sown in May or June.

C. nobilis.—This seems closely akin to *C. punctata*, and has red-violet or white flowers. It does not appear to be very perennial, and should be propagated by seeds or division. Twelve inches to 18 inches high. June and July.

C. patula.—A rather coarse native, about two feet high, with panicles of purplish blue flowers. Division or seeds. Partial shade. July.

C. persicifolia.—The most valuable of the taller Campanulas, *C. persicifolia* is now most varied in appearance and in colouring. It grows from

2 feet to 6 feet or more in height (we have seen *Moerheimi* about seven feet), is from white to deep blue, and the flowers, opening in June and July, vary greatly in form. Some are broad and flat, others are longer, while some are of the calycanthema or "cup-and-saucer" type, the calyx being of the same colour as the corollas. The double varieties are very handsome, and the old *C. p. fl.-pl.* has been superseded by newer varieties. *Moerheimi* is one of the finest double whites, *humosa* being a charming blue one, but there are many other good varieties. Division or seeds. Plant in good soil.

C. primulæfolia.—This was a biennial with the writer, and is not of much value. From 1 foot to 3 feet high, with a spike of purple flowers. Seeds. July.

C. pulcherrima.—Very like *C. elegans*.

C. pyramidalis.—A well-known pot or border plant, known as the Chmney Campanula. It

SOME GOOD
BORDER CARNATIONS:

- | | |
|-------------------|--------------------------|
| 1. Firefly. | 3. Mrs. H. Brotherstone. |
| 2. Goldilocks. | 4. Daisy Walker. |
| 5. Queen Eleanor. | |

is unnecessary to say anything regarding it, except that it is not often long-lived in the border, and is best treated as a biennial. Flowers in the open in July. Sow in May.

C. rapunculoides.—A rather coarse native species, with spikes of drooping blue flowers. Inclined to run at the roots, though not so much so as *C. Rapunculus*. Division of seeds. July.

C. Rapunculus.—This should be banished from every garden, so troublesome does it become. It grows from 1 foot to 4 feet high, and is blue. July.

C. sibirica.—From 12 inches to 18 inches high and with panicles of drooping violet flowers. *C. sibirica* suffers from being only a biennial. The form *divergens* is pleasing, while *C. s. eximæa* is a choicer plant in every way, with violet flowers also. Seeds. *C. Hohenackeri* is practically a form of this, with violet flowers. June and July.

C. Trachelium or C. urticæ-folia.—The Nettle-leaved Bellflower is a rather coarse but useful plant for the border. The flowers are blue or white, and are in good spikes. The double form, *C. Trachelium fl-pl.*, and its white variety *alba* were at one time much cultivated, but they are now less frequently seen. Comes freely from seeds and grows anywhere. Height from 1 foot to 4 feet. June and July.

C. Tymonsi.—A pretty hybrid about a foot high, with spikes of light blue flowers. Said to be of the same parentage as *C. Hendersoni*. Division or cuttings. June.

C. van Houttei.—A handsome hybrid for the border or rock garden, and with good purple flowers. Common soil. June and July.

C. versicolor.—There are three *versicolors* in the trade, one a poor biennial, 3 feet or so high, with small blue flowers; another, a pleasing pale blue subject about a foot high, but a shy bloomer; and a third about a foot high with blue and white flowers. July.

C. Vidali.—A lovely shrubby species with succulent, glossy foliage and charming pale blue flowers in July and August, but only of value in the warmest parts of England and Ireland. Seeds or cuttings. One foot to 2 feet high.

ANNUAL CAMPANULAS.

These call for little notice, and the prettiest are *C. drabæfolia* or *attica*, a charming dwarf hardy annual only a few inches high. *C. Loreyi* or *ramosissima*, 6 inches to 12 inches high, blue; and the handsome *C. macrostyla*, purple, with ornamental projecting styles, are good border plants. *C. dichotoma*, *C. Loefflingii*, *C. phrygia* and *C. strigosa* have all been in cultivation, though it is not easy to procure seeds of these. Sow in the same manner as other hardy or half-hardy annuals

S. ARNOTT

COLOURED PLATE.

PLATE 1480.

HARDY BORDER CARNATIONS.

AFTER dealing so frequently with the Tree or Perpetual-flowering Carnations, it is a pleasant change to place before our readers some up-to-date varieties of these hardy border favourites, blooming as they do in great profusion from June until November, and bred to endure the most rigorous winter. The five varieties of which a coloured plate is given

A DELIGHTFUL BELLFLOWER: CAMPANULA PERSICIFOLIA HUMOSA

Glow-vented carnets that has proved the most popular of the year. Award of merit of the Royal Horticultural Society, July, 1912.

Queen Eleanor. This lovely Mr. Douglas considers his best introduction to this class. A lovely apricot ground, edged and suffused with nervy scarlet, fading to blood red. One of the most frequently exhibited flowers of the past two years.

Goldilocks is a self of the true apricot shade and of perfect form, and, owing to its robust constitution, is a valuable addition to this popular colour.

Daisy Walker.—This is the white-ground fancy that gained the coveted distinction of a first-class certificate of the National Carnation Society last July, and won for its raiser the challenge trophy. It is, no doubt, the last word in this increasingly popular type, its ground a pure white, barred and pencilled a rosy scarlet, and by unanimous opinion judged to be the best-shaped white-ground variety extant. The stock of this is to be distributed in 1914, and is held by Mr. J. Douglas, Edenside, Great Bookham, to whom we are indebted for the flowers of all the five varieties from which our coloured plate was prepared.

THE GREENHOUSE.

EARLY TULIPS IN POTS.

TWO or three "things to know," culled from my own experience, may happen to be useful to some who are growing these early varieties.

(1) I find that I am more successful with them when I place the pots in a cold frame with a dark covering over the lights than if I "plunge" them in anything. I am able to so manage things that air can be, and is, given, except in very severe weather, all day and night. This is very necessary. (2) I believe that a considerable time may be gained if the newly-potted bulbs are placed in darkness under the staging or elsewhere in a warm greenhouse where the temperature can be kept about 50°. They come on very quickly in such positions, and as it also draws up the foliage, they can remain there a certain time after top growth has commenced.

Unfortunately, during this period green fly is apt to be extra troublesome, and a constant watch has to be kept for its unwelcome appearance, when prompt steps must at once be taken to send the little pests about other business.

(3) People frequently complain of some of their Tulips flowering low down close to the soil without any length of stem. This often arises from dryness at the roots at some period of their growth, for no plants are more susceptible to a want of adequate moisture than Tulips. It may be, however, their innate habit which requires correcting by a course of dark confinement in the earlier stages of growth. Some, such as Prince de Ligny

with this issue were raised and distributed by Mr. James Douglas of Great Bookham, who for a quarter of a century has been engaged in improving this type.

Firefly, a bright scarlet of perfect shape and ideal border habit, was exhibited at the Royal Horticultural Society's meeting in July last, and received a unanimous award of merit.

Mrs. Andrew Brotherstone.—No painting can do justice to the quaint beauty of this remarkable flower, its petal being perfect and the outline of the flower rivaling the *Gardemia* in shape, the colour a mode carmine, curiously and beautifully spotted with white markings. A powerfully

and Prince of Austria, do not want it; others, for example, Proserpine and Yellow Prince, do.

(4) There is no doubt that size of bloom and size of pot are almost interchangeable terms. By the application of manurial aids extra size can be obtained when the plants are overcrowded, but it is at the expense of their habit. I like to see well-developed leaves just as much as fine flowers, and that is why I am always preaching against overcrowding. Long, delicate-looking, weakly leaves are unnatural, and any treatment that tends to produce such must be dealt with as one proverbially does with poison. For example, Van Goooven, one of the cheapest of all the early varieties, is remarkable for its handsome foliage—broad, large and very silvery. The flower is like a medium-sized pale Cottage Maid, borne on long, sturdy stems. Overcrowding would entirely alter its character, and a lovely plant would be spoilt.

JOSEPH JACOB.

THE AMATEUR'S GREENHOUSE IN AUTUMN.

By now all tender subjects that it is desired to keep throughout the winter should be under cover, as sharp frosts may set in at any time. With so many plants for which to provide accommodation, there is a great tendency to overcrowd the greenhouse, and if this is carried to the extreme, failure in many cases must be anticipated. Plants that have been outside for some time will often have a few destructive insects or slugs thereon, and for this reason every one should be carefully examined before they are taken indoors, even then some may be overlooked, and such as aphides or green fly readily increase when subjected to warmer conditions. Should there be the least sign of these pests, a very good plan is to vaporise with one of the nicotine preparations that are now to be obtained, as vaporising is much safer and gives less trouble than when fumigating is resorted to.

Another point to bear prominently in mind is that the plants which have been out of doors, perhaps for months, have been fully exposed to the air, so that, when they are taken into the greenhouse, that structure should not be kept too close, otherwise many subjects may be injuriously affected. If this is not attended to, some even of the evergreen subjects will lose a good many of their leaves. It is, therefore, evident that a reasonable amount of air must be left at all times on the greenhouse, provided there is no actual frost, though direct draughts must, as far as possible, be avoided. Watering, too, is also another important consideration, for whereas in the height of summer it is best done, in the evening, so that the plants may imbibe moisture during the night, it should now be carried out in the morning, in order that the superabundant moisture may be quickly dried up. At this season of the year, too, plants dry much less rapidly than in the summer, and consequently will not need so much

attention in this respect. The various subjects that go wholly or partially to rest naturally require much less water at this season, but those of an evergreen nature must always be kept moist. To this section belong such subjects as Azaleas and Heaths, as well as the different plants in flower. Chrysanthemums whose blooms are expanded or rapidly approaching that stage are very liable to decay if there is a spell of damp weather and too much atmospheric moisture in the structure. In this case a good plan is, even if the weather is fairly warm, to use a little fire-heat, and this, combined with a liberal amount of air,

season, the temperature may without risk descend to 45° at night, rising during the daytime.

Fuchsias lose their leaves during the winter, and when dormant they require very little water, only just sufficient to prevent them being parched up. They will also do with a moderate amount of light, on which account they are, in order to economise room, often wintered underneath the stage of the greenhouse. This has one marked drawback, inasmuch as they get the drip from the stage when the plants thereon are watered.

Pelargoniums of the Zonal and Ivy-leaved sections that have been bedded out during the summer should be lifted, shortened back, the long, straggling roots cut off, and be potted in comparatively small pots or laid thickly in shallow boxes. If they are given a good watering when first potted, no more will be required for some time, as these Pelargoniums need but little water during the winter months, for they are better if kept dry and in a partially dormant condition. This, of course, does not apply to those that are to flower in the winter, as for them increased heat and water are very necessary. In any case, Pelargoniums should have as light a position as possible, a remark that also applies to Heliotrope and Verbena. For those that are more or less dormant, such as Lantanas, Cannas, Agapanthus and Hippeastrums, light is not so essential. It is a great advantage to frequently shift the plants about, as by passing them through the hand any signs of decay or other troubles may be detected, and as far as possible remedied. Above all, never leave decaying foliage on the plants or lying about in the house. H. P.

THE NEW PRIMULA LA LORRAINE

will serve to dissipate the excess of moisture. At the same time, too dry an atmosphere must be avoided, as it is decidedly injurious to plants in general. Should frost penetrate into the greenhouse, do not on any account rush up the temperature by means of fire-heat, but cover up the structure so that the plants are in the dark, and allow them to thaw gradually. The different flowering subjects, such as Carnations, Zonal Pelargoniums and Primulas, need a light, buoyant atmosphere and a temperature of 50° to 60°. Where the greenhouse, however, is not regarded so much for the production of blossoms in winter as a structure for keeping tender plants safely through that

well-known *P. obconica*, but so far without success; indeed, it is doubtful if any species has been crossed with *P. obconica*. The leaves of the hybrid under notice are soft and woolly, and the flowers are of the pure Rose du Barri colour. The plant seen in the accompanying illustration was shown by Mr. M. Pritchard, Christchurch, before the Royal Horticultural Society in the spring of this year, when it received an award of merit. It is a variety of great promise, by virtue of its exceptional colour, neat habit and freedom of flowering. Only this one plant was shown, but, should its seed prove fertile, there is little doubt that this acquisition will soon be in the hands of many cultivators.

PRIMULA LA LORRAINE.

This new hybrid will be welcomed by those who cherish the uncommon and beautiful forms of the genus *Primula*. The newcomer is of Continental origin, and is said to have originated from the crossing of *P. Veitchii* and *P. cortusoides* americana. The two parents resemble one another fairly closely, so that it is not surprising to learn that the cross has been effected. Incidentally, it might be mentioned that frequent attempts have been made to cross *P. cortusoides* with the

GARDENING FOR BEGINNERS.

HOW TO FORCE LILY OF THE VALLEY AND FLOWER ROOTS.

THE work of forcing flowering plants is very fascinating, and claims the attention of cultivators throughout the winter months. Heat and moisture, and a somewhat confined atmosphere are essential to success. The heat must be artificial, secured from fires and hot-water pipes, or from hot-beds, or both. Moisture is easily obtained, and it must not be excessive, unless the heat is also high. The confined atmosphere is secured in a deep frame, pit or low house.

Lilies of the Valley.—These are forced by placing plump crowns in pots, or clumps containing a number of good crowns. The best are Berlin crowns or the strongest selected English-grown ones. Although few new roots are made during the forcing process, it is very detrimental to allow the crowns and roots to get dry at any time. While in a dormant condition the crowns will not be injured by exposure to frost, but they must not be lifted from the ground nor placed in a warm temperature while in a frozen state. Wait until all frost has disappeared naturally. A light, sandy compost is best for Lily of the Valley when potting up the crowns or clumps. No. 1, Fig. A, shows a strong crown, and No. 2 the same one with a portion of the roots cut off to enable the workman to place the roots properly in a flower-pot. No. 3 represents a useless crown. A few of these are generally found in the clumps, but they must not be removed, as they do no harm, and provide leaves for cutting purposes when the flower-spikes are placed in vases. No. 4 shows a good clump. Few roots are too long for potting conveniently when pots are used large enough to permit of the fingers being inserted between the clump and the sides. A nice sandy soil can easily be worked in among the roots. Single

SELECTING AND POTTING UP LILY OF THE VALLEY CROWNS.

crowns must be potted as shown at No. 5. Twelve or more crowns may be placed in a 6½-inch pot. When the space, No. 6, has also been filled with crowns and some of the compost, strike the pot sharply on the bench, keeping the fingers on the crowns to steady them. This will have the effect of firming the soil around the roots, and any open space can then be filled at the top. No. 7 shows

the stage of growth when the plants can be taken from the covering material. No. 8. No. 9 depicts the pots in a frame before being covered with moss or Cocoanut fibre. No. 10 shows a strong crown and flower-spike. At this stage full light must be admitted to them.

Fig. B represents flower roots, such as Spiræas, Dielytras and Solomon's Seal. Roots of moderate size may be potted whole; large ones should be divided. It is not necessary to put a great bulk of soil round these roots when they are potted. From three-quarters of an inch to an inch of compost will be sufficient. Thorough drainage and firmness of soil are necessary. Directly the roots are potted, give them a good watering. No. 1 shows a clump that is of suitable size to pot singly. No. 2 represents a large root that should be divided as denoted by the dark line across it. No. 3 shows half of a divided clump placed in a pot, and No. 4 the space to be filled with the prepared soil. No. 5 also gives a top view of the same root as placed in the pot, and No. 6 represents a whole, but smaller, root as potted. No. 7 shows a root of Dielytra spectabilis, and No. 8 one of Solomon's Seal. The large roots in each case must be carefully preserved in the pot. Until the time comes for placing the roots in a warm house, keep them in a cold frame as shown at No. 9. The latest batch of plants will commence to grow in such a frame. When the flower-spikes become prominent and new roots plentiful, put the pots in saucers as shown at No. 10.

Feeding and Watering. Spiræas, Dielytras and Solomon's Seal may be both fed and watered through the medium of saucers. All the forced plants must be gradually subjected to a cooler or greenhouse temperature after being kept in a high one for a time; then the leaves and flowers last longer in a fresh condition. G. G.

DIVIDING THE ROOTS OF SPIRÆAS, DIELYTRAS AND SOLOMON'S SEAL BEFORE POTTING UP.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Flower Garden.

The Herbaceous Border.—By this date practically all the late-flowering plants will have gone out of bloom or been cut down by the frost; hence the need to go over the border, cutting down what is necessary and making the whole quite tidy for the winter. Where no replanting or digging is to be done before the spring, a light pricking over of the surface will improve the appearance of the border.

Biennials.—It is not too late, providing the weather is open, to put various biennials and perennials in their flowering positions; in fact, some plants stand the winter better after being shifted than when left where they have originally been pricked out; so that Sweet Williams, Anchusas and Canterbury Bells may still be planted in the borders or beds. I find these subjects have made an unusual amount of growth this autumn, and may be the better for the check.

The Rock Garden.

Additions and Alterations.—The next month or so is, I think, the best time to make additions and alterations in the rock garden. By making the alterations at this season, the rocks and soil have time to settle into what will eventually prove their normal position before planting is done, probably in early March.

The Position of the rock garden has a very great deal to do with the ultimate success of the plants. It is useless to expect alpine plants to flourish in a position where even grass will not grow, and it is often in such a place that a heap of soil is put and stones dumped on to it, with a few Ferns put in, this being called a rock garden. To succeed in the cultivation of alpine plants generally, the position cannot be too open, the natural formation of the garden and the grouping of the stones providing the shade that is so necessary for the cultivation of certain subjects; and in an open position it is quite easy to have a bank facing each of the different points of the compass. Do not try to make a rock garden under trees, nor partially so.

Plants Under Glass.

Chrysanthemums.—By this date many of the early-blooming Japanese varieties will be over. These should be got rid of as soon as possible, and so make room for other subjects. Many of the stools may be thrown away at once, reserving only those that are required for stock purposes, thus saving a good deal of labour in shifting them about from place to place. A good light position is the best for stock plants, and a frame where frost can be excluded by turning on a little heat is very suitable. The latest batches of decorative varieties should be spaced out as much as possible, disbudbing some of them to one bloom to each shoot, Mrs. J. Thomson, the Victoria family, J. W. Crossley, Winter Cheer and Heston White all giving better results when treated in this way.

Salvias and Eupatoriums for spring flowering must be given plenty of space between them just now, or the growth is likely to become attenuated. Careful feeding is necessary to maintain them in a healthy condition without unduly softening the growth. In each instance plenty of water is required, these being very tree-rooting subjects.

Perpetual-Flowering Carnations.—The plants at this season must be kept very steady. Any endeavour to force them either with heat or manure is bound to end disastrously, at least so far as the ultimate success is concerned. A dry atmosphere is essential, as also is a moderately dry condition of the roots. In the event of much fire-heat being required to keep the temperature from 45° to 50°, spider may make its appearance, but a careful spraying now and again should keep it under.

Arum Lilies that may have been kept in the frames till now should be removed to a house, and if the flowers are required about Christmas-time, an intermediate temperature will suit them well. If late bloom only is required, they will do equally well in a cold resting fruit-house.

Plumbago rosea. To get the best returns from this beautiful plant, it should be kept growing

right through the winter, and must, therefore, be kept in the cool end of the stove; or if an empty Cucumber or Melon house is available, it can have exactly the treatment it requires. Naturally, as the plants come into flower, too much atmospheric moisture should not be maintained, though a damping between the pots should be given on all fine mornings. This is necessary to keep the plants growing, and so maintain a succession of bloom.

The Kitchen Garden.

Broccoli.—A sharp eye must be kept on these, so as to cover them up or lift them as soon as they are fit for use, or the first sharp frost will spoil them. A good way to treat a batch just coming in is to put the fork underneath them and give the plants a good heel over. In this way it takes a great deal more frost to injure them than when standing upright.

Globe Artichokes will be the better for a little protection from severe frost. Good, dry leaves placed around each clump, finishing off with some long, strawy manure, will keep them in good order; but care must be taken not to cover the clumps entirely, or rotting will take place.

Hardy Fruit.

Pears.—A few early varieties that do consistently well in this neighbourhood are Citron des Carmes (very small), Clapp's Favourite, Souvenir du Congrès, Beurré Giffard, Dr. Jules Guyot and Williams' Bon Chrétien. These are well worth planting, all of them giving fair crops practically every season, Clapp's Favourite and Dr. Jules Guyot being perhaps the most consistent. Doyenné Boussoué, though not first-rate in flavour, is a heavy cropper every year, and is well worth growing for early stewing. Pitmaston Duchess always gives a fair crop of good clean fruit, as also do Beurré Diel, Marguerite Marillat and Beurré de Mortillet. Marie Louise and Doyenné du Comice are not so consistent, but the fruits are usually clean and of good flavour. Thompson's, when established, crops very freely, and is one of the best Pears we have for flavour. Good late varieties are Charles Ernest, Marie Benoist, Nouvelle Fulvie and Le Lectier, the latter always giving a fair crop of clean fruit which keeps and ripens well.

THOMAS STEVENSON.

(Head-gardener to E. Mocatta, Esq.)

Woburn Place Gardens, Adlestone, Surrey

FOR NORTHERN GARDENS.

The Flower Garden.

Protecting Tritomas.—These showy autumn flowers can only be looked upon as hardy in very favoured localities, and I fear they often suffer more or less for lack of a little attention at this time. Some dry, open litter or coal-ashes should be placed round them, and the operation had better be performed by two persons, one to gather up the long leaves and hold them up, while the other manipulates the protecting material.

Old Violas.—While second year plants cannot be relied on to go through the summer, yet they yield large quantities of bloom throughout the spring months before young stock begins to make much of a show. It is well, therefore, to make use of some portion of the old plants for this purpose. When they must be moved from their present quarters, they can be lifted and replanted in ground which is to be used for half-hardy annuals next season. The varieties of *V. cornuta*, if cut down now, can be relied on to go on flowering throughout the whole of next summer.

Viola gracilis.—This little gem should be freely used. It can either be propagated by cuttings or by division.

The Rose Garden.

Planting.—This work must be prosecuted with vigour, in order to enable the plants to get somewhat rooted before severe weather sets in. Roses suffered sadly during November last year.

Replanting.—Notwithstanding every attention, Roses (on clay subsoils especially) often flower less freely after they have been planted for a few years. When such is the case, it is advisable to lift the entire bed or border, cut back the long, bare roots, and lay them in the ground temporarily in a convenient spot until the bed or border has

been prepared for their reception again. If some fresh loam can be procured, it will be a valuable asset. Dress with some well-rotted farmyard manure, adding some bone-meal, wood-ashes and lime. Bastard-trench the ground, and, after it has been allowed to settle for a few days, replant the Roses, making any desired modifications as to the varieties and their arrangement. Give the whole a mulching of some light, open material.

The Pleasure Grounds.

Gravel Walks.—Old walks that have been frequently gravelled and have become rather unsightly can be improved without much expense by the following means: Begin at an end and slacken the surface with a pick to the depth of 3 inches or 4 inches; then pass the loose material through a sieve with a quarter of an inch or three-eighths of an inch mesh into a wheel-barrow, and wheel away the earthy siftings. Level the remaining material, which will soon be made clean and fresh by the winter rains.

Mulching Rhododendrons.—Large specimens will be much benefited by receiving a good mulching of half-rotted farmyard manure. Not only will they assimilate its fertilising properties, but it will assist in maintaining those cool conditions at the root during the ensuing summer which they so much enjoy.

Plants Under Glass.

Chrysanthemums.—The Autumn Queen now reigns supreme, the admired of all admirers, and cultivators are reaping their reward. Now is the time for note-taking, both at home and by the exhibition table. The big blooms are being slowly ousted by the decorative and the singles. It is some consolation to know, however, that with such varieties as Felton's Favourite, David Ingamells, Mrs. A. T. Miller, Nelly Pockett, Soleil d'Octobre and Market Red one may secure a large number of good-sized blooms on a plant.

Sweet Violets.—These will now require careful handling, damp being the great enemy. To dispel it, the plants must be ventilated freely on all favourable occasions, while, on the other hand, they must be carefully protected from frost. Pinch all runners as soon as they appear.

Orchids.—Dendrobiums, Cœlogynes, Cattleyas and many other species of Orchids which naturally go to rest at this season should have the temperature considerably lowered, and they should enjoy rather dry conditions both at the root and in the atmosphere.

Fruits Under Glass.

Forming Vine Borders.—Where Vines are to be planted next spring, a start should be made with the border as soon as possible. For early work it is better to have the border inside only, but for general purposes it is advisable to have the border partly inside and partly outside.

Tomatoes.—Where winter Tomatoes are grown, a temperature of about 60°, with a rather dry atmosphere, should be maintained, and the flowers be artificially pollinated as they open.

The Hardy Fruit Garden.

Pruning Currants.—The work of pruning Currants should now be proceeded with. Red Currants should be pruned on the spurring system. Black Currants bear on the previous season's wood; therefore some portion of the old branches should be cut away annually to make room for young wood. The young shoots should only be slightly shortened.

The Vegetable Garden.

Potatoes.—Potato pits which were left open on top to allow evaporation to proceed should now be finished off, and some protecting material should either be placed on the pits or be at hand in the event of severe frost occurring.

Laying Savoys.—Much of this useful winter crop is often lost on account of the rains and melting snow percolating down among the leaves and lodging in the axils. This evil can be largely obviated by hitting the crop and laying it in by the heels, laying the plants well over on their sides so that they can throw off the water.

New Zealand Spinach can generally be kept in condition throughout November by covering a portion of the crop with a frame, or even by matting it on frosty nights.

THE KITCHEN GARDEN.

SEASONABLE NOTES ON VEGETABLES.

Cabbages.—No time should be lost in putting out the last batch of plants to come in for use in June. Such varieties as Flower of Spring, Daniels' Defence, Wheeler's Imperial and Sutton's Imperial are all suitable. At this season slugs are especially troublesome during showery weather, and if not checked will quickly spoil the whole plantation. Lime and soot is of little use, as the first shower destroys its power. A much better remedy is to cover the ground within 6 inches of the plant, and close up to the stem, with finely-sifted coal-ashes. Over this slugs cannot crawl. All established plants should have the soil frequently stirred with a Dutch hoe, or, in the case of stiff soil, fork it lightly over in dry weather. Frequent stirring of the soil is also a check to slug depredations.

Onions.—Those who wish to produce large exhibition bulbs next year would do well to make a start in preparing the land on which they are to grow. In the growth of Onions of the Ailsa Craig type deep cultivation is an absolute necessity. An open site, away from overhanging trees, should be selected, and the land trenched quite 3 feet deep. If the soil is of a stiff, retentive character, with a hard pan-like subsoil, into which the roots cannot enter, but which withholds superfluous moisture from heavy rains which are not beneficial to the growth of the Onion, thoroughly break up the bottom trench and add a layer of manure to every spit of soil, using that which is long at the bottom; this assists in maintaining porosity of the soil. The shorter manure should come near the surface. If there is a possibility of the ground being trenched again next year, I would advise that the soil from the bottom of the trench be brought to the top; if not, arrange to have the surface soil in the same position when the trenching is completed. Leave the surface as rough as possible. The winter frosts will disintegrate the clods and render the soil in good working condition. Choose dry weather for the work, or the soil will knead too much.

Tripoli Onions.—The plants resulting from seed sown in August will now be 2 inches or 3 inches high. Keep them free from weeds by constantly hoeing during dry weather. First give a good dressing of soot or wood-ashes, which will, when hoeing, be gradually worked into the soil, and will in due course be beneficial to the plants in their subsequent growth.

Globe Artichokes.—Remove the lower leaves preparatory to placing around each a thick mulch of long, strawy manure as a winter protection from frost. In low-lying districts where the plants suffer from frost and fog, it is a good plan to take off and pot up sucker-like growths, wintering them in a frame with their pots plunged in ashes. Keep the lights open during fine weather to induce a stocky growth. Such plants will be useful in making a new plantation or for filling up gaps.

Endive should be transferred to frames as fast as they become empty to keep up a succession of blanched heads. Well ventilate the frames to prevent the rotting of the outside leaves. Blanching may still be done by tying up the largest plants of the Batavian kind out of doors. The Moss-curved should be blanched by the aid of an inverted flower-pot, covering the drainage hole at the same time so that all the light is excluded. Three or

four weeks are required to blanch Endive properly. As the days become colder, the most satisfactory way is to lift a few plants every week and place them in the Mushroom house, shed or cellar.

Celery.—The final earthing should not be delayed after this date. As the work proceeds, carefully tie the leaves close to the stem to prevent the soil getting into the heart of the plant, which makes crooked sticks and cripples the growth generally. Well break up the soil, making it quite fine before placing it around the plants. If it is put together in rough lumps, that also, by undue pressure, creates a crooked growth. After the soil is chopped down from the sides of the trenches, and before it is put around the plants, soot should be liberally sprinkled on the soil as a check to slugs disfiguring the Celery. For earliest use, blanching with brown paper is the more simple way and quite as efficient. Where this is employed, and the weather at all dry, the plants should receive another, and last, soaking of water. Afterwards apply the last rings of paper, making them all secure.

Cucumbers for winter use must have close attention in their growth requirements. Abundance of heat is an absolute necessity, never allowing the thermometer to fall below 70°. The plants will not need syringing, but moisture must be maintained by damping the walls and beds occasionally. Remove any leaves showing the slightest tendency to red spider or mildew. Keep the growth thin on the trellis, stopping the shoots at the second joint, and by no means crop the plants heavily, or they will quickly collapse; if not quite that, the fruit will decay at the point, become crooked, or refuse to grow altogether. Never allow more than one fruit to remain from any cluster of flowers. Cover any roots with warm soil as fast as they appear on the hillocks, and always use tepid water when moistening the roots.

Swamore Park, Hants.

E. MOLYNEUX

ANSWERS TO CORRESPONDENTS.

FLOWER GARDEN.

TULIPS FOR MAY (Manners).—The best Tulips for your purpose will be varieties of the Cottage or May-flowering sorts and those known as Darwins. The last named are the tallest and most handsome, though some of the shades of colour you require are not found in this group. Those most likely to suit you are Clara Butt and Inglescombe Pink, which really constitute the best pinks, with Inglescombe Yellow, Mrs. Moon and Leghorn Bonnet, yellow. Bouton d'Or is late flowering and very rich in colour. If you keep the bulbs of these in a cool, dry cellar or similar place until mid-December before planting them, a later flowering would be assured. Spanish Irises should follow the Tulips for early June. These should be planted at once. We think such Roses as Aglaia, American Pillar, Hiawatha and Tausendschön would be most suitable. The earliest-flowering Gladioli among large-flowered sorts are those known as July-flowering. They are a varied and delightful class.

DAFFODILS AND PÆONIES (M. A.).—Daffodils are chiefly increased by means of offsets, i.e., side shoots which appear on the parent bulbs. These, when large enough, may be detached, and replanted either with the parent plant or in a place apart. Daffodils are also freely raised from seeds; but as the seedlings take from four to a dozen years before flowering, and a very considerable proportion of them may be inferior to the original, this phase of the subject will be hardly worth your while. You ask whether the herbaceous Pæony is long-lived, and the answer is that we believe it will, with cultivation, continue indefinitely. Indeed, we have to-day plants of a variety which grew in the home garden in established clumps fifty years ago, and the day of deteriorating is not yet. It should be remembered, however, that the plants have been cultivated meanwhile, and, this done, they may remain good for years. Good cultivation includes lifting, dividing and replanting every few years, say, six to ten, according to the circumstances. The Pæony is a deep-rooting, gross-feeding subject; hence deeply-trenched, well-manured soils should always be given it. The best planting season is September and October. Large clumps of the Pæony

should never be transplanted intact, free division of the roots being as essential to the future success of the plant as the other things mentioned. In soils that are both light and shallow, six years would be ample to have them without division, while in deep, rich loams they may remain for twice as long and still furnish good flowers.

TREES AND SHRUBS.

PRUNING BUDDLEIA VARIABILIS AND TAMARIX (Mrs. F. Browne).—The Buddleia should be cut back fairly hard, preferably early in the spring. The Tamarix may be cut back at the same time if it is desired to keep it within bounds; but, if a big bush is required, it would need no pruning at all, except to remove weak shoots that might be killed by the frost.

TREES AND SHRUBS FOR EAST COAST TO GROW IN SAND (Dolphin).—The following subjects may be expected to thrive under the conditions you describe: Pinus Laricio and its variety nigricans, the Corsican and Austrian Pines respectively, Scots Pine (Pinus sylvestris), Goat Willow (Salix Caprea), S. caicera, S. repens, Hippophaë rhamnoides, Tamarix in variety, Cinnamo Bireh and Picea sitchensis. All the plants must be inserted while quite small, and the Pines will establish themselves most successfully if planted when from 6 inches to 12 inches in height. For shelter there is nothing better than Austrian Pine.

TO PRUNE POLYGONUM BALDSCHUANICUM (A. D. H.).—This plant may be cut back to within a few buds of the main branches, and have a number of the latter cut away if there are too many any time during winter or early spring, preferably during February or March. It is usual at the present time to go over plants and remove any growth which is likely to cause inconvenience during the winter, reserving the main pruning for the spring.

FRUIT GARDEN.

NEGLECTED FRUIT TREES (Bono).—The best way will be to go over the trees at once. In the first place, cut out all the dead branches and twigs (these, of course, can be of no good). Then start again and cut out the weakest of the branches where the tree appears overcrowded with them. That will be all you need to do now, but some time in January go over the trees again and thin out more of the weakest and most worn-out looking branches; that is to say, if you think the trees are still over-congested with branches. There is no other pruning necessary except this thinning out, and this should be seen to every winter. The middle of November transplant the Raspberry canes from where they are not wanted into rows where they are wanted. You will be disappointed if you leave the Rhubarb in the cellar for another year. Take it out and replant it in the garden, filling its place in due time with fresh roots from outside.

ABOUT APPLES (H. G.).—The Apples are badly attacked by the scab fungus. During the winter thoroughly prune out all the shoots (spurs and weak shoots are both liable to attack) showing cracks in the bark. Spray the trees while dormant with a wash of lib. of copper sulphate to 25 gallons of water. Just before the buds burst, and again after the petals fall, spray with Bordeaux mixture of half the strength used for spraying Potatoes. Almost any Apples except the most vigorous-growing varieties will succeed as cordons. They should, of course, be on Paradise stocks. Worcester Pearmain, Colonel Vaughan, Emperor Alexander, King of the Pippins, Cox's Orange Pippin, Allington, Golden Reinette, Baumann's Reinette, Fearn's Pippin and Sturmer Pippin for dessert purposes; and Duchess of Oldenburg, Potts' Seedling, Grandeur, Stirling Castle, Golden Spire, Lord Derby and Bismarck among kitchen varieties, would probably prove satisfactory.

MISCELLANEOUS.

TO REMOVE CLOVER FROM TENNIS LAWN (G. G.).—Give the lawn a dressing of sulphate of ammonia in spring at the rate of 1½wt. to the acre. Basic slag would greatly increase the tendency to grow Clover.

PLANT FOR NAME AND TREATMENT (Miss R. S. L.).—The specimen sent for determination is the Variegated Tree Mallow (Lavatera arborea variegata). It is a biennial, and is propagated by seeds, which may be procured from most of the best firms of seedsmen at about one shilling a packet. It is not usual for every plant to come true from seed, although a good percentage have variegated leaves.

NAMES OF PLANTS.—A. K. B., Surrey.—Clerodendron foetidum (a Chinese shrub).—*Fife*.—1, Aster Novæ Angliæ pulchellus; 2, A. N.-A. ruber; 3, A. Indeyanum. 4, A. Novi-Belgii Robert Parker; 5, Zebraia pendula. 6, Phlox reclinata; 7, 8, 9 and 10, garden forms of Clematis Jackmanii; 11, Aster Novæ Angliæ variety.—*Exmo*.—The Dahlias are as follows: 1, Henry Patrick; 2, A. D. Stoop; 3, Rev. A. Hall; 4, Mrs. J. Goddard; 5, Mrs. Macmillan; 6, Crescent; 7, too poor to recognize.

NAMES OF FRUIT.—T. C.—1, Withington Filibasket; 2, Kedleston Pippin; 3, Ecklinville Seedling; 4, Hawthornden; 5, Betty Geeson.—*Dinnet*.—Wykeo Pippin.—*J. A. W.*—1, Tibbett's Pearmain; 2, Fearn's Pippin; 3, Pearson's Plate; 4, Marill; 5, Bess Poul; 6, Peasgood's Nonsuch.—*A. R. T.*—1, Keswick Codlin; 2, King of the Pippins; 3, Hollandbury; 4, Warner's King; 5, Potts' Seedling; 6, Lord Derby; 7, Pennington's Seedling; 8, Miller's Seedling; 9, Hoary Morning.—*J. E. P.*—1, New Hawthornden; 2, Frouzere Prolife; 3, Cox's Orange Pippin; 4, Cellini; 5, Royal Nonsuch; 6, Allen's Everlasting; 7, Beauty of Hants; 8, 9 and 10, King of the Pippins; 11, Stamford Pippin.

SOCIETIES.

THE KENT COMMERCIAL FRUIT SHOW.

THE third annual exhibition of commercial fruit, organised by the Kent Commercial Fruit Show Association, was held in the Corn Exchange, Maidstone, on Tuesday and Wednesday, October 28 and 29. The number of entries were well in advance of those in previous years, and although the fruit was not so well coloured, in most instances it was of excellent quality. This show has rightly come to be regarded as a centre for the exhibition of the best examples of British-grown Apples and Pears, and, by bringing to the notice of consumers, growers and salesmen the merits of good grading and packing and the production of clean, sound fruit, those responsible for the display are doing good work. The exhibition and luncheon were attended by a great many people, among them being the Agent-General for Victoria, Australia, who stated that he had never seen such good fruit in the country that he represented.

We do not here propose to give details of prize-winners in the various classes, as these are of interest only to those connected with the trade, but it may be of value to give a brief review of a few of the more outstanding features. It was interesting to note that in the culinary Apples Bramley's Seedling and Newton Wonder were the most extensively shown. The classes for these were particularly well filled, and some extremely fine examples of these fruits were on view, both in boxes and barrels. The boxes used had to be of the following size, inside measurement: Federation standard, 20 inches long by 11 inches wide by 10 inches deep; Federation half-box, 20 inches long by 11 inches wide by 5 inches deep. Exhibitors were also advised to use boxes made to the following specification: Heads in one piece, three-quarters of an inch thick; sides in one or two pieces, three-eighths of an inch thick; tops and bottoms in two pieces, a quarter of an inch thick; and cleats for tops and bottoms about a quarter of an inch thick by 1 inch wide by 11 inches long. Good grading and packing had to be taken into consideration by the judges, and a class was specially set apart for the best packed boxes in the show. In the dessert Apples there were some very fine displays of Cox's Orange Pippin, Allington Pippin and Blenheim Orange, the latter, in many instances, being particularly well coloured, in spite of the fact that Apples, generally, are of a very dull hue this year. In the class for a new dessert Apple, introduced since 1900 and in season after December 1, Rival was about the only variety of import shown, the special cup offered in this class being awarded to Messrs. Gaskin and Whiting for a magnificent box of that variety. Evidently it is to be one of the leading dessert Apples of the future.

The barrels of culinary Apples, such as Bramley's Seedling, Newton Wonder and Lane's Prince Albert, were exceptionally good, those holding about three bushels being favoured. Here, in some instances, notably in Bramley's Seedling, fruits of two grades or sizes were shown, and the packing was plain evidence that some at least of our home growers have little to learn from those in the Colonies.

The Coupe Challenge Cup and the silver-gilt medal presented by the Worshipful Company of Fruiteers, offered for the best exhibit in Classes 1, 2, 3 and 4, respectively, devoted to Bramley's Seedling, Newton Wonder, Lane's Prince Albert and Blenheim Orange, grown in Kent, Surrey or Sussex, were won by Mr. S. Skelton, West Farleigh, Maidstone, for a wonderfully good display of Bramley's Seedling. The George Menck Smith Champion Cup, offered for the best box shown in Classes 1 to 15, was won by Messrs. Gaskin and Whiting, Faversham, with a superb box of Cox's Orange Pippin, this box being sold by auction for three guineas. The silver medal presented by the Worshipful Company of Fruiteers for the best box shown in Classes 13, 14 and 15 went to Messrs. F. and E. Le Feaver, Marden, Kent, for a splendid box of Lane's Prince Albert.

Two fine non-competitive groups of fruit were shown. One of these was from Messrs. George Bunyard and Co., whose head-quarters are at Maidstone, and who have a world-wide reputation for fruit trees. This comprised all the leading varieties of Apples in the pink of condition, and staged in the firm's best manner. The other came from Messrs. Seabrook and Sons of Chelmsford, and was also of particularly attractive appearance, fine, well-filled fruits, particularly the Cox's Orange Pippin, being arranged to the best advantage. Grading machines and spraying apparatus of many and up-to-date kinds were well shown by Messrs. Drake and Fletcher of Maidstone, and it is evident that the commercial grower is much better catered for in this direction than he was some years ago. The Best Grading Machine was also shown at work by Messrs. W. Weeks and Sons, Limited, of Maidstone, who also showed large spraying machines.

Messrs. E. and A. White, Limited, Paddock Wood, Kent, had a fine display of their famous "Ald" insecticides, fungicides and washes, as well as spraying apparatus of many and particularly effective kinds. Their new non-poisonous worm-killer was also on view.

The Four Oaks Spraying Machine Company, Sutton Coldfield, had a very wide assortment of their spraying machines and apparatus, suitable for both large and small growers, and it would be difficult to name anything of the kind that they could not supply. Messrs. Voss and Co. of Millwall, London, made an attractive display of chemicals for spraying purposes, and also included samples of their well-known Fertilisers.

A deputation of the Royal Horticultural Society, consisting of Mr. James Hudson, V.M.H., Mr. W. Poulton, Mr. A. H. Pearson and Mr. C. G. A. Wix, visited the show on the first day and made the following awards to the exhibitors on behalf of the society: Gold medal to Messrs. Gaskin and

Whiting for their collective display of Apples and Pears; silver-gilt Knightian medal to Messrs. George Bunyard and Co. and to Mr. Miskin; silver-gilt Banksian medals to Messrs. W. Seabrook and Sons, Mr. S. Skelton and Messrs. Spooner and Co., the latter being for maiden trees; silver Banksian medals to Messrs. W. Ray and Sons for maiden trees; Messrs. H. Cobb for three boxes of Allington Pippin; Mr. G. E. Champion, Mr. F. Smith and Messrs. Skinner and Sons. With such an important exhibition as this being held annually, we would suggest to the committee of management that invitations be extended another year to representatives of the horticultural Press.

READING GARDENERS' ASSOCIATION.

THE usual fortnightly meeting was held in the Abbey Hall, by kind permission of Messrs. Sutton and Sons, on Monday, October 27, when, owing to the enforced absence of the president through indisposition and of the chairman (Mr. Powell) in consequence of the serious illness of Mrs. Nolle, Mr. J. T. Tubb (vice-chairman) presided over a good attendance of members. The lecturer for the evening was A. Harrison, Esq., of Watford (late of Onghia, Italy), and his subject "Orchids." The lecturer first pointed out by the aid of lantern-slides the structural peculiarities of the flowers of Orchids and their resemblance to many insects, such as moths and butterflies. The extraordinary form of the fruiting organs, the means whereby insects were attracted and used for the purposes of pollination and intercrossing, were also shown by slides of *Coranthes*, *Stanhopes*, &c. Mr. Harrison then went on with plates and descriptions together, giving cultural details of the most useful species, such as might be grown successfully in warm, intermediate or cool greenhouses in the company of ordinary plants usually found in such structures, provided a few essential details were observed. He emphasised the importance of the use of rain-water only, as well as of careful ventilation, stating that while movement of air was absolutely necessary, nearly all the species objected to draughts. Most of the air admitted should come through ventilators below the stages, and not at the stage level. It was pointed out how excess of ventilation at the apex of a house dissipated the moisture and unduly dried the atmosphere, to the detriment of the plants. Among the species for warmer houses, of which slides were shown, Mr. Harrison included *Cattleya Mendelii*, *Triniae*, *labiata*, *gaskelliana*, *gigas*, *harryana* and *aurea*; *Laelia purpurata*; *Dendrobium nobile*, *crassinode* and *warhanum*; *Cypripedium lebanum*, *Charlesworthii*, *bellatulum*, *fairbankianum*, *callosum*, *Sanderi* and *Carlsoni*. Plates were also shown of some of the newer beautiful compound hybrids of *Laelia-Cattleya*, *Odontodia*, *Brassia-Cattleya* and *Brassia-Laelia*, and the lecturer stated that the great vigour of many of these hybrids made them more amenable to cultivation than a number of the species, but added that the prices of many were prohibitive. Among species needing cool treatment, plates of *Odontoglossum crispum*, in many varieties, were shown—*O. Hallii*, *O. harrayanum*, as well as many hybrid *Odontoglossum* and *Cypripedium insigne*. Seedling *Cypripedium* were also shown growing on the compost of an established plant, and the various methods of raising Orchid seedlings were described. At the conclusion of his remarks Mr. Harrison answered numerous questions put to him by members of the audience, and at the close of the meeting was accorded a most hearty vote of thanks.

The hall presented an exceedingly bright and gay appearance, as, apart from specimens of Orchids brought by the lecturer, there were no fewer than eight exhibits. Mr. G. Tovey, The Gardens, Leighton Park School, staged eighteen dishes of fine Apples, which were awarded a certificate of cultural merit and were also judged for the Points Competition. For the latter three fine collections of *Chrysanthemum* were put up by Mr. J. T. Tubb, The Gardens, Bearwood; Mr. H. Reeves, The Gardens, Blandford Lodge; and Mr. H. G. Cox, Mr. E. Blackwell, head-gardener to the Lord Chief Justice, staged a collection of well-grown Apples, and Mr. H. Goodger, The Gardens, Stanham House, three baskets of fine Sutton's Ailsa Craig Onions, which secured almost the maximum number of points. From the University College Gardens Mr. Drew sent beautiful *Chrysanthemum*, and Mr. W. Lees exhibited a group of seedling *Fuchsias*. Two new members were elected. The hon. secretary acknowledges with sincere thanks the receipt from "Onlooker" of two five-pound notes, to be devoted to special objects. The committee will consider and endeavour to carry out the donor's wishes.

BOURNEMOUTH HORTICULTURAL SOCIETY.

THE Council of the Bournemouth Horticultural Society held a most successful exhibition of fruits, flowers and vegetables in the Westover Palace Skating Rink on Tuesday and Wednesday, October 28 and 29. The groups, cut flowers of *Chrysanthemum* on boards and in vases, the fruit and vegetables, and the non-competitive exhibits made the chief features of the exhibition. The children's section was also an extensive, beautiful and instructive one.

GROUPS OF MISCELLANEOUS PLANTS AND CUT FLOWERS.
Mr. Usher, gardener to Sir Randolph Baker, Bart., was the winner in the big group class. His *Crotus* and Orchids were very effective. Messrs. G. Watts and Sons, Limited, Bournemouth, were close second prize winners, staging lovely *Begonias*, *Crotus*, *Palms* and *Ferns*. Mr. J. Stevenson, Wimborne, had a lovely group of plants and *Chrysanthemum*, and won third honours.

Mr. Charles Pearce, gardener to Mrs. Ormrod, won the cup offered for a group of Japanese and single-flowered *Chrysanthemum*. His group was charmingly arranged.

CUT FLOWERS ON BOARDS AND IN VASES.

For twenty-four Japanese in not fewer than eighteen varieties, Mr. J. H. Tooley, gardener to Mr. Hugh Andrews, Winchester, won, having the examples of His Majesty,

Queen Mary, Aber Lemon, Master James (highly coloured), Kara Dow, Frances Jolliffe and Lady Talbot. Mr. Usher was second, his blooms of Bob Pulling, Mrs. A. E. Roope, F. S. Vallis, W. Turner and D. B. Crane being very fine. Third honours went to Mr. B. Daere, gardener to Mr. W. Dickinson, Taunton. Master James and Pickett's Crimson were his best blooms.

Mr. Usher had the best Japanese incurved blooms, H. E. Converse, W. Turner and Mrs. A. E. Roope being the best. Messrs. Daere and Tooley were second and third respectively.

That fine cultivator Mr. H. Woolman of Shirley, Birmingham, won in the class for nine vases of blooms on long stems, distinct, three blooms in a vase. His blooms of C. H. Totty were very fine. He had also in good form Thomas Lunt, Miss Gladys Herbert, Lady Talbot, Lady Crisp and Kara Dow. Second honours went to Mr. J. Stevenson, Wimborne, who staged very nice blooms. Mr. Tooley was placed third.

In the class for two vases, nine blooms in each, two varieties, Mr. E. G. Cox, gardener to Mrs. Dunbarley, was placed first with F. S. Vallis and Mrs. Marsham. Mr. Kitcher, gardener to Major Wyndham Pain, was second with W. Turner and Mrs. Marsham, and had the best blooms. His blooms of W. Turner were the finest in the show.

For six vases, Mr. Galpin, gardener to Mrs. Teffer, was the winner. He had the best single vase of Japanese yellow, six blooms in a vase, Mr. Cox having the best six white Japanese.

Singles were well shown. Mr. Honey, gardener to Mr. J. G. Rayner, winning in the class for six vases. Mr. Bargo, gardener to the Rev. C. H. Burrows, was successful in a similar class in another division.

Mr. Usher won in the class for winter-flowering Carnations, and Mr. Short won the cup in the class for *Begonias* and winter-flowering plants.

Messrs. G. B. Heath, Webb and Weaver staged the best Zonal *Pelargonium* in the order named. These made a brilliant display near the centre of the hall.

FRUIT AND VEGETABLES.

The Grapes, Apples and Pears filled one long table, the quality throughout being very good. The Muscat of Alexandria Grapes were of the highest quality and grandly coloured. Mr. Hall of Embury Park, Romsey, Mr. Hill of Kingston Lacey, and Mr. Tooley of Winchester, also Mr. Barnett of Bournemouth, were the chief prize-winners.

Messrs. Cope of Wimborne Hill, Daere and Usher were the principal winners in the classes for Apples and Pears, and Mr. Usher had matters all his own way in the vegetable classes, winning the first prizes offered for collections by Messrs. Sutton and Sons, Messrs. Webb and Sons, and Messrs. Toogood and Sons.

NON-COMPETITIVE EXHIBITS.

Gold Medals.—To Messrs. John Waterer and Sons for shrubs and chambers; Messrs. G. Watts and Sons for *Chrysanthemum*, hardy shrubs and floral designs; Messrs. Stuart Low for Orchids and Carnations; and Messrs. James Carter and Co. for vegetables.

Silver Medals.—To Mr. J. J. Kettle for Violets; Messrs. Toogood and Sons for vegetables; and Mr. Robert Chamberlain for floral designs.

WARGRAVE GARDENERS' ASSOCIATION.

A LARGELY-ATTENDED meeting of the above society took place on Wednesday evening, October 22, when "ten-minute papers" were given by Mr. Baker on "The Propagation of Stove and Greenhouse Plants," Mr. Pritchard on "Tomato Culture," Mr. Irvin on "Large-flowering *Cinerarias*," and Mr. Gray on "Violet Culture." Each subject was treated in a very practical manner, full cultural directions being given, and a capital discussion ensued after each paper. Votes of thanks were carried with acclamation at the close. Three new members were elected. The Wargrave Plant Farm, Limited, staged a splendid lot of outdoor *Chrysanthemum*, and the judges awarded a cultural certificate. Mr. Pope showed a group of *Begonia Gloire de Lorraine*, Mr. Mackenzie a vase of Dahlias, and Mr. Stephens a vase of Carnations, and all three were highly commended.

ELSTREE AND BOREHAM WOOD HORTICULTURAL ASSOCIATION.

THERE was a large gathering of members of this society in the Parish Room on the evening of Thursday, the 16th ult., the occasion being that of a presentation to Mr. W. J. Pritchard, the hon. secretary of the society. The chair was occupied by the Rev. A. R. T. Eales, who said that it was one of those happy occasions when everybody was of one mind. They had met there to show their appreciation of the splendid work which their hon. secretary had rendered their society. Mr. F. Jones, who was secretary to the Testimonial Fund, said that 101 members had contributed to the fund, and spoke of his esteem of Mr. Pritchard. Mr. Harman Moore and Mr. T. Eales also spoke in glowing terms of the excellent work which Mr. Pritchard had done, and his keen interest in the affairs of the village. The presentation, which took the form of a magnificent roller-top desk, was formally presented by the Rev. A. R. T. Eales, who fully endorsed all that had been said of Mr. Pritchard. Also at the same time Mrs. Pritchard was presented with a handsome gold guard chain. In thanking the chairman and members, Mr. Pritchard, speaking with emotion, said that his work as hon. secretary had been very largely a labour of love, and he certainly did not look for any acknowledgment. The presentation was followed by a musical programme, kindly arranged by the chairman and some of the members, the evening being brought to a close by accorded musical honours to Mr. Pritchard.

EDITORIAL NOTICES.

Every department of horticulture is represented in **THE GARDEN**, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in **THE GARDEN** will alone be recognised as acceptance.

Office: 20, Tavistock Street, Covent Garden, W.C.

NOTES OF THE WEEK.

A Brilliant Torch Lily.—The variety *Nelson* is one of the most interesting of dwarf-growing varieties of *Kuhpohias*. It is not more than 2 feet high, very floriferous, and has elegant grassy foliage, against which the bright flame-coloured blossoms contrast admirably.

Useful Flower for Cutting.—*Helopsis scabra* exceeds as a dwarf-growing form of this autumn-flowering subject, much in advance of the ordinary type. The blossoms are quite circular, thoroughly lubricated, and of a rich orange yellow colour. Early in June the flowers open, and they last quite fresh until the end of September—a remarkably long period. In a cut state flowers of this variety have been known to last six weeks in a fresh condition.

Rolling Lawns.—There is a tendency at this season to overlook the immense value of rolling lawns. This is really very essential, and now that the lawns are not being mown, the heavy roller should be used as often as possible, more especially while the weather is open. A loose-surfaced lawn is productive only of soft and easily-damaged grass, while a lawn that is kept quite solid by regular rolling produces finer grass, which will stand much more wear.

Potentilla Gibson's Scarlet.—For its colour alone this remarkable plant should be grown by all, the dazzling or brilliant scarlet of its flowers being probably unique. The plant, too, is a great bloomer, of ideal hardiness, not given to fastidiousness, and, being comparatively dwarf-growing, is useful in the small or the large border. At no time is the herbaceous flower border overdone with scarlet; hence so good a plant is doubly welcome. Increased by division or by seeds.

A Chinese Shrub with Black Fruits.—So many of our ornamental fruiting trees and shrubs have red, orange or yellow fruits that those with fruits of some other colour should receive consideration. Though of little or no value as a flowering shrub, *Eleutherococcus* (*Acanthopanax*) *Henryii* has very ornamental black fruits in autumn. Growing about five feet in height, the bushes are very attractive in autumn when laden with closely-packed heads of jet black fruits. There are also two other species with ornamental black fruits, natives of China, viz., *E. leucorrhizus* and *E. sessiliflorum*. A shrubby border containing these and other fruiting shrubs has many admirers.

The Strawberry Tree (*Arbutus Unedo*).—This subject surpasses many other shrubs from an ornamental point of view. It flowers at a time when the majority of other shrubs have long passed. It is interesting as one of the very few plants that bloom at the same time as they bear the fruit of the previous year. At this time of the year it is laden with its terminal, racemose panicles of white flowers and its Strawberry-shaped scarlet fruits, both of which are very handsome.

Its variety *rubra*, generally known as *Arbutus Crooni*, is an even more desirable plant, with much larger flowers of a beautiful rosy carmine colour and larger, dark green foliage.

A Beautiful Late-Flowering Monkshood.—A plant worthy of a place in the herbaceous border is *Aconitum Autumn Glory*, a beautiful late-flowering variety of the well-known *A. chinensis*. The flowers are not only later, but larger and of a lighter blue. A colony of this plant flowering at the present time is very interesting.

Protecting Dwarf Roses.—In gardens near the coast, dwarf Roses do not often suffer from the effects of frost, but in many localities it is an annual struggle to bring many varieties of Teas and Hybrid Teas safely through the winter; and as severe frost may now occur at any time, it is well to be prepared. The aim should be to break the current of cold air and still afford the plants a certain amount of air and light. For this double purpose Bracken or Wheat straw littered loosely in among the plants will be found very suitable.

Winter-Blooming Wallflowers.—Plants of the Early Paris Wallflower raised from seed sown last May are now giving their fragrant flowers. But it will be found advisable to cut the first spikes, as it encourages the plants to send out side growths, which will soon produce flowers and continue throughout the winter, providing the weather is not severe and the plants are given a warm, sheltered corner. These plants, if lifted carefully now and put in pots, will make valuable subjects for decorating the conservatory or cold greenhouse.

Sea Holly with Tall Stems.—The Sea Hollies, or *Eryngiums*, are quite an interesting family of plants, many of them being of an ornamental character. One of the most conspicuous at the present time is *Eryngium pandanifolium*. It might well be called a hardy *Pandanus*, or Screw Pine, which it very much resembles with its handsome rosettes of glaucous leaves. At the present time it is bearing its tall panicles of flowers, which are arranged in globose heads of a purplish colour, and often attain a height of from 10 feet to 15 feet.

A Spiræa for the Rock Garden.—There are not many *Spiræas*—herbaceous or shrubby—that one would care to recommend for cultivation in the rock garden, though in the case of *S. digitata nana*—provided the true plant is obtained—it may be done with absolute confidence. In other words, this very charming plant, of not more than 9 inches high, is in the nature of an alpine, and because of its dwarfness and effective appearance is well suited to associate with alpine vegetation. The true plant is probably still quite scarce, and spurious forms have been distributed. No one, however, having once seen this pretty variety, endowed with dainty flowers of soft rosy pink, would ever forget its elegant beauty. The plant should be given a position of uniform coolness or moisture. Best increased by division in spring.

CORRESPONDENCE.

The Editor is not responsible for the opinions expressed by correspondents.

The Almond in Scotland.—Referring to the note by "Caledonia" on page 558 of November 8 issue, the common Almond is quite hardy in this district, and there have been trees in the locality for many years. I grow the double variety in this garden, where it has been for more than eight years. The dwarf Almond is also hardy, and I have cultivated both it and the variety *bessermana* for a long time.—S. ARNOTT, *Sunnymead, Dumfries.*

Treatment of *Dracæna australis*.—As an experiment, I planted out in the open garden a *Dracæna* last year. The soil here is a very heavy, cold clay, and I was rather afraid the *Dracæna* would suffer and probably rot off at the roots. The only protection it had was some straw at the base and some old sacking wrapped fairly tightly round the plant. On April 20 of this year I took off its "winter coat," and it has thrown some splendid new spikes. True, last winter was a mild one, with no prolonged spell of frost. Perhaps this accounts for its survival.—T. C. F. M., *West Horsham.*

ago in Gunnersbury House Gardens, Acton, where *Nerine Bowdenii* thrives in company with the *Belladonna Lily* under a sunny greenhouse wall and makes a most interesting feature.—C. Q.

Bracken as a Vegetable.—On reading in the *Times* of November 3 about the destruction of Bracken, I thought what a great pity it is (especially in these "vegetarian craze" days) that the value of young Bracken fronds when 3 inches to 6 inches high is not more generally known here as it is in India and Japan, for, instead of wasting and destroying the plants, it would be sent to market bundled as Asparagus is, and would furnish a welcome addition to our springtime vegetables. I append the method of cooking, which I have tried and proved to be successful. Take young, closely-curl'd Bracken fronds when about three inches to six inches high (or a little more), choosing the thickest and most green and tender ones. Stand the freshly-cut ends for about two hours in water in which a little ordinary kitchen soda has been dissolved. This draws out any slight occasional bitterness and generally improves the flavour. Rinse the stems in fresh water. Tie lightly in bundles, and proceed to cook and serve

I wonder if other readers of your widely-read paper have had the same experience. The plants are two years old from the date of sowing. It has never been out of bloom, but certainly has been improving. It takes a long time to ripen its seed, and yesterday was the first time I was able to gather any."

Lime-hating Campanulas.—Yes; the history of my relations with *Campanula pulla* is precisely as Mr. Murray Hornbrook has guessed (see page 546, November 1 issue). I followed blindly and faithfully the authority of Mr. Robinson, doing absolute reverence to his word in default of any correcting experience of my own. And the reward of my piety was long and sedulous failure, broken only by brief and partial gleams of success. I still did not dare to trace these tragedies to any source of error at the fountain head, nor did the various florists that include *C. pulla* give any enlightening indication. But in 1911 I went East into the Styrian limestones for *Dianthus alpinus* and *Primula clusiana*. The first bonus that that astounding mountain yielded me in the first five minutes was *Campanula alpina*; the second, *Viola alpina*; and the third was *Campanula pulla*, growing along the fallen limestone blocks in the black humus of a little gully. I came home enlightened; from that moment *C. pulla* throve with me in a mixture of peat with my ordinary loam. But the next year I again returned to Styria, and this time, higher up the mountain, I found *C. pulla* in wide mats in the limestone screes below the summit ridge, luxuriating here in a stiff and heavy yellow loam devoid of any element of peat. So now I take no further thought at all for *C. pulla*. It goes straight into my ordinary rock garden soil, in any cool ledge desired, and there it straightway increases and runs riot like a happy weed. With regard to *C. excisa*, I am not at all sure that this plant is not really a much more untractable lime-hater than *C. alpestris* (*Allionii*). It grows best in absolutely pure granitic sand among river boulders high up on the northern and the southern slopes of Monte Rosa. In cultivation, Mr. Bowles has made it an irrepressible weed in a bed of beautiful spongy, loose soil—two parts coarse sand and one part of riddled leaf-mould—with water flowing beneath. With me, however, this treatment has not yet answered, and my best patch gives me the lie at present by sprouting voluminously in a part of the bed devoted to lime, in chips and rubble, for the benefit of *Saxifraga burseriana* and *C. Zoysii*. With regard to Mr. Arnott's series of notes on *Campanula*, it is ungracious to look so charming a gift-horse in the mouth; but in the interests of those lovely plants themselves and their worshippers, I must really be allowed to ask for fuller descriptions if these are to be of general help, and also to suggest that too faithful and unconsidered a following of catalogue names, when the original authorities lie so ready to hand, is not the best way, perhaps, of rescuing us from that sea of confusion in which catalogues have plunged us. For some instances, in one page: *C. stenocodon* has no reference to *C. pusilla*, but is a variety or subspecies of *C. rotundifolia*; *C. tridentata* is specifically different from *C. Saxifraga*, and easily recognisable; *C. valdensis* is another subspecies of *C. rotundifolia*—this is the downy plant, with big purple bells. But Mr. Arnott's account of its second "form" looks very suspiciously like the genuine *C. caespitosa* (Scop.), which Mr. Arnott has so cruelly wronged by obliterating it into the name of the wholly different *C. pusilla* (Hænk.); and, finally, I shall be interested to learn how the true *C. uniflora* resembles *C. excisa*.—REGINALD FARRER.

NERINE BOWDENII FLOWERING IN THE OPEN AT GUNNERSBURY.

Nerine Bowdenii Flowering Out of Doors.—There appears to be a general impression that Nerines are tender subjects, only to be grown under glass, and the recent observations in the columns of THE GARDEN all tend to support this view. For instance, Mr. F. Herbert Chapman writes on page 534, October 25 issue: "it would be well if some of the amateurs who now devote the whole of their glasshouses in autumn to Chrysanthemums could be induced to take up Nerines," and he overlooks the fact that at least some of the Nerines may be grown entirely out of doors. Mr. Elwes, in his widely-appreciated article which appeared in your issue for September 13, says: "In the warmest parts of England Nerines may be grown fairly well in a cold frame all the year round, but in my experience better in pots than planted out, as I have never seen them in perfection so treated." One is led to wonder if Mr. Elwes has planted out of doors the comparatively new but very charming *Nerine Bowdenii*, which, by the way, he does not consider a desirable parent of hybrids owing to the irregular shape of the perianth segments. That this species will not only grow, but will flower profusely out of doors is clearly shown in the accompanying illustration. This was taken a few weeks

exactly like Asparagus, which it greatly resembles.—ANNE AMATEUR.

Primula Poissoni at Clandon Park.—On November 9 we were privileged to see *Primula Poissoni* flowering in great profusion in the *Primula Dell* at Clandon Park. This recent introduction from China is evidently a vigorous grower, but its great value is seen in the masses of lilac purple flowers that are produced over a long season. Mr. Blake, the able gardener of Clandon Park, who takes the greatest pride in the hardy *Primulas* grown there, writes: "I am sending you a few flower-spikes of *Primula Poissoni*. Now, these have been in flower continuously since April; in fact, the flower-spikes were cut down by the last frost we had late in April. The spikes were then about a foot high. Since that time they have continually thrown up spikes of bloom, and never has the bloom been shorter than at the present time. Moreover, the colour is deeper than at any time during the summer. What to me is the most wonderful of all is that new flower-spikes continue to be thrown up in all stages. Of course, the first stiff frost will settle matters effectually; but, so far as my experience goes, there is no *Primula* that flowers as freely and continuously as does this one.

COPRINUS COMATUS, A FUNGUS THAT SECRETES A FERMENT USED AS A CURE FOR SILVER-LEAF DISEASE.

Rose Chateau de Clos Vougeot.—This fine Hybrid Tea Rose was very good in the second week in October in a Dumfriesshire garden high up among the moors and hills, and, apart from its beauty, it has the possession of fragrance in a degree not often to be found among the newer Roses. It is one of the most fragrant of Roses, and one of the most delightful of the dark varieties of its class. It may be too deep in colour for the taste of many who prefer light-coloured Roses, but it is such a good Rose that it deserves consideration. It is well described as velvety scarlet, shading to fiery scarlet and changing to dark crimson. It is a capital bedding Rose, and flowers freely and long, and is such a favourite in the garden referred to, where good Roses are appreciated, that it is to be more largely grown. It was sent out in 1908.—S. ARNOTT.

War on Wasps.—Regarding the plague of wasps and the remedy, we have found it very successful to offer prizes at our local flower show for the greatest number of queen wasps and the greatest number of nests. If the prizes are fairly good, there are plenty of entries. In the case of the wasp nests, they were not exhibited at the show, but brought in as found to a member of the committee, who credited the bringer with the number and burnt the nests. Over fifty were taken round this house, with the result that, as far as we were concerned, we had no plague, although a mile away it was the worst year on record.—EDWARD M. HADOW, *Uffington Vicarage, Berks.*

— In reference to Mr. Copeland's question, No. 3, under the above heading, page 534, the following note may be of interest to him: We had matted some Currant bushes to preserve the fruit. On uncovering one of them rather late in the year, I found a large number of queen wasps in the folds of the mat. It is a good many

years since, and I cannot now say with certainty how many there were. Being in a semi-torpid state, they were easily disposed of. It is well known that queen wasps often take shelter during the winter in any warm, dry article that happens to be hanging undisturbed for a time, so it might be worth while to loosely fold pieces of garden matting or sacking and place them where they can be kept dry. If the experiment does not succeed as regards wasps, there will certainly be some earwigs.—THOMAS SMITH, *Westbury-on-Trym.*

A Wallflower for Bedding.—To those on the look-out for a first-class plant for bedding or massing, and one out of the ordinary, I can strongly recommend *Cheiranthus Allomii*. It commences to bloom in May, and, providing it is kept from seeding, will continue to give masses of its sweet-scented orange blooms the whole summer long. Although a perennial, I always treat it as a biennial, planting out strong seedlings each autumn 1 foot apart. It is a plant that requires a fair amount of manure, with an occasional dusting of a good artificial during the summer. Treated thus, the blooms will be twice the size of those one generally sees on plants growing on rockeries. For massing in front of borders it is fine, its beautiful orange colour blending well with all its neighbours, and its agreeably sweet scent invades the whole garden. We grow a variety called *C. superbus*, a much improved form sent out by Messrs. Barr.—F. WOODS, *Hatfield Park.*

The Best White Rose for Bedding.—I have just received my September 6 edition of THE GARDEN. I notice Mr. Molyneux asks for ideas as to which is the best white Rose for bedding. After considering the notes made by Mr. Molyneux, may I place my choice as follows: Elaine, The Bride, Mrs. Foley Hobbs and Molly Sharman Crawford? The first-named Rose does well with me, and I have a nice bed of it. The plants are very floriferous; the blooms come a lovely shape. They are not such a pure white as the other three mentioned, being very slightly tinted cream, but the plants make a fine bed. The Bride is grown out here very extensively on its own roots, and a bed of it in February—our best flowering month—is a sight. Kept low it is splendid, but it is inclined to make rather a big bush with us. The last two mentioned I have only had for two seasons, but I should say they would be very good white bedding Roses in the United Kingdom. They make nice beds with me, and I have had some fine blooms from both. White Maman Cochet we all know, but the drooping habit of the flower debars it from being a good Rose. My Roses are grown in a temperature varying from 60° to 88° Fahr. and within 20 yards of the sea. As to the last statement I am well aware, for on September 18 a typhoon swept away over two hundred of my favourites.—R. A. NICHOLSON, *Hong Kong.*

FORTHCOMING EVENTS.

November 15.—Royal Horticultural Society's Exhibition. Chrysanthemum Show at Wokingham.

November 19.—Jubilee Show at Bristol (two days). Shows at Newcastle (two days), Woolton, and Hull (two days).

November 20.—Norfolk and Norwich Chrysanthemum Show (three days). Shows at Barnsley (two days) and Paisley.

November 21.—Shows at Dundee, Blackburn, Bolton, Dunfermline, Stockport (all two days) and Kilmarnock.

THE SILVER-LEAF DISEASE OF FRUIT TREES.

ITS CAUSE AND PREVENTION.

THIS disease, well known to attack and even to destroy the Plum, especially in the case of certain varieties like the Victoria and Czar, is easily recognised by a silvery of the upper surface of the leaf, from which it takes its name. It is a condition which may be due to different causes, but which, in probably 99 per cent. of cases that occur among fruit trees, is due to a common fungus, known as *Stereum purpureum*. The spores of this fungus are able to grow wherever they find a wound; they soon germinate, and give rise to a mycelium or spawn, strictly the same as the spawn of Mushroom, which travels through the wood and in a short time affects the leaves. It does not follow that the spawn itself has reached the leaves, for the effect, in the case of a Victoria Plum, has been produced at a considerable distance beyond the region attained by the spawn or mycelium. In the case of one experiment, out of fifteen inoculations made in February, twelve resulted in silverying by the middle of May. An inoculation of a Victoria Plum in August, 1912, resulted in silverying five weeks later. This common cause of silverying—indeed, quite the commonest—was made known by Percival in 1902. (See *Journal of the Linnean Society*, Vol. XXXV., page 390.) Since then other experiments have been made, particularly by Mr. F. T. Brooks, M.A., of the School of Botany at Cambridge, and it is one of his remarkable demonstrations in the Cambridge Botanic Garden that leads to this note. In a group of young trees the silvered branches are easily picked out from among others that bear only green, healthy leaves, and, by following the shoot down, there is invariably found the label which records inoculation.

STEREUM PURPUREUM ON STEM OF APPL. THIS IS THE FUNGUS THAT CAUSES SILVER-LEAF DISEASE.

Silver-leaf a Comparatively Recent Disease.—

It is remarkable that until recent years little notice appears to have been taken of this disease. I find no remark about it in works I have on fruit cultivation; indeed, in Thompson's "Assistant" it is said that the Plum is liable only to gumming. The true cause at first does not seem to have been accepted. It was pointed out in 1902. In 1906 Dr. Cook, in "Fungoid Pests of Cultivated Plants," page 135, says: "We must still regard ourselves as sceptical as to whether *Stereum* is the cause of silver-leaf"; and Mr. Masee, in the same year, says: "I know absolutely nothing about silver-leaf." In 1908, in Messrs. Bunyard's Nursery, I believe by Mr. Bunyard, jun., I was informed that silver-leaf was due to injury. This was near the mark, but mechanical injury by itself is unlikely to produce such a result, and only an agent like *Stereum* was required to complete an explanation.

Other Causes of Silver-leaf.—It may be said now that this cause has been proved for Plums, and that no other is known, though cases have occurred which do require another explanation. Mr. Brooks mentions the silverying of seedling Plums which could not be attributed to the action of *Stereum*, and it is unlikely to cause silverying in the case of the White Dead Nettle. It has been known, too, in the case of Apple shoots which have been cut from healthy trees and kept in the air for a short time. While not the cause in these instances, it may reasonably be regarded as the cause in the case of certain trees and shrubs that are not allied to the Plum, as, for instance, Red Currant and Laburnum, upon which the sporophores or fructifications of *Stereum* were found. Laburnum, indeed, has been silveryed by infection from the Plum, and a Whinham's Industry Gooseberry bush, inoculated during 1911, became silveryed during 1912. *Stereum* may thus affect a variety of trees—Portugal Laurel I remember to have suffered in this garden—and it is important to mention that although Mr. Brooks has seen few adult Apple trees showing silver-leaf, he has frequently found scions of regrafted trees that are silveryed. He describes a group of Blenheim Orange Apple trees that were regrafted with scions of either the Grenadier or Jubilee variety three years ago. The grafts grew until the spring of 1912, when those on twelve of the trees rapidly died. When the trees were examined in August, 1912, each stock showed innumerable sporophores or fructifications of *Stereum purpureum* growing from the bark. It should be remembered that while silver-leaf in a fruit tree may be held almost with absolute certainty to indicate the presence of *Stereum*, it does not follow that that *Stereum* necessarily produces silver-leaf. Mr. Brooks believes that the manifestation depends partly upon leaf structure, and in cases mentioned silver-leaf did not result, though *Stereum* had made considerable progress in the tissues. Apple and Beech trees that were probably killed by *Stereum* did not show the phenomenon.

R. IRWIN LYNCH

Botanic Garden, Cambridge

(To be continued.)

ROCK AND WATER GARDEN.**THE DESIGNING, CONSTRUCTION AND PLANTING OF ROCK GARDENS.**

IF there is one subject that has, more than others, received too much attention from a journalistic point of view, one would think it is that of the rock garden and its kindred associations. Volume on volume, article on article, have been poured forth in season and out of season, all professing to deal with one phase or another. Where there is such an unlimited supply of literature on one subject, it is possible, even probable, that some of it gets read. I do not propose to apologise for adding to the pile, because, although one may choose to write, it is by no means a guarantee that there are those who will choose to read. Those who do not will need no apology. Those who do have it in their power to curtail the perusal of these articles at the exact point at which they

THE BEGINNING OF A ROCK GARDEN.

This stone, weighing 779 tons, and containing 9,720 cubic feet, was the result of blasting out stone for rock gardens at the Stancliffe Quarries, near Darley Dale, Derbyshire.

cease to interest them. May I say definitely here what I believe to be the real and most important faculty that is necessary for the successful arrangement of not only rock and water gardens, but every other form of landscape treatment. It is a sense of, and power of, composition—the power to judge of the sympathetic and harmonious relation of one feature to another, whether it be masses of rock, grouping of shrubs and trees, combination of colour, or the association of other suitable vegetation. However, despite the fact that this sense is lacking in many of us, there are, I believe, some simple rules that, carefully followed, render it quite possible for most of us to construct a successful rock garden, that may possess many faults, it is true, but that will not only provide many happy hours, but also (but not by any means the least of the uses of a rock garden, but one that is, unfortunately, often overlooked) a happy home for the innumerable species and varieties of alpine plants now in cultivation. It is my intention to

take the reader through the elementary processes of preparing such a garden in the sequence in which they would arise in the progress of the work, viz., (1) Selection of site and design; (2) Selection of stone; (3) Arrangement of stone; and (4) Soils and planting.

Choice of Site.—Mr. William Robinson has given it as an axiom that the rock garden should be "as far removed as possible from the house," and I remember he took particular care to impress this on me during a brief conversation I had with him at the International Show at Chelsea last year. Now let me say at once that there is no man living (perhaps few dead) to whom, in my opinion, the horticultural world owes greater respect, admiration and gratitude than to Mr. Robinson, and none shares more ardently in the general tribute paid to his work than I do; but I think this particular assertion of his is calculated to be a little misleading. The rock garden should be in the most suitable position, even though the drawing-room window looks straight upon it, and the most suitable position is determined not by the proximity to the house, but by the application of a harmonious design to an applicable site. True, it frequently happens that the most suitable site occurs at a point that is a considerable distance from the house, because, generally speaking, the further one gets from the domicile the nearer one gets to natural conditions, and, consequently, the more at home seems the rock garden; but it is not imperative that natural conditions should in every case be driven to the furthest extremity of the grounds, whether it be of mansion, villa or cottage. I have recently come across charming dells and sloping banks in quite close proximity to the residence of the owner that were ideal situations for the introduction of rock outcrop among masses of low-growing shrubs and other plants. It is quite impossible to enumerate all the sites that are suitable, so it will be better to look at some of them in combination with the question of design. There is (and reference to the best-known authorities will verify this) a particular style of formation that is so eminently suitable for any given site that in nine cases out of ten the environment itself determines the ultimate design, and the only satisfactory method of illustrating this will be to take actual conditions with which I have personally come in contact, and by description and a few simple sketches place before readers the best method of achieving the most successful results under those conditions.

Colchester.

GEORGE DILLISTONE.

(To be continued.)

LITHOSPERMUM PROSTRATUM FLOWERING LATE.

THIS lovely rock plant is still blooming away, unharmed in its flowers by frosts, which have cut down the Dahlias and have injured some of the Chrysanthemums. Other rock plants in bloom are few and far between, but *L. prostratum* is quite happy, and is giving quite a number of its fine blue flowers. It is so frequently mentioned that one need do little more than call attention to its late flowering.

Dumfries.

S. ARNOTT.

A QUANT AND INEXPENSIVE SUNDIAL.

THERE was a time when the sundial was introduced into the garden for the purpose of measuring the time. To-day it has become merely a garden ornament, a centre from which diverging paths radiate, or the central axis of a formal design. It introduces into the garden a more or less romantic note of association with the past, and appeals to the same sense of appreciation as old buildings, old furniture, and everything else that has come to us from bygone days. The sight of one calls up memories of the sweet old-world flowers of Chaucer and Shakespeare: the Sweet Brier, Pinks, Giliflowers, Lavender, Rosemary, Columbine, and "Roses damask and red" of Bacon.

The design for a sundial pedestal in the accompanying illustration is not meant for the garden

attractive. The same idea can be successfully adopted to create pedestals for small lead figures, and can easily be worked into circular, hexagonal or octagonal shapes. Old bricks and tiles are recommended, not because they are cheapest, but because the discolouration of age on them gives the best results. A sundial plate can be obtained for a few shillings, and even though it was made in Birmingham last week and will probably bear a date about 1647, no one will mind the date being false; in fact, if a genuine *old* dial were obtained, who would believe in its antiquity?

SECTIONAL DIAGRAM OF SUNDIAL PEDESTAL.

productions of its raisers. It is not easy to find a fault with it. A good grower, flowers of excellent shape and refined character, deep cream in colour and fragrant. Hardly subject to mildew. Very strongly recommended to the exhibitor.

Margaret (William Paul and Son, 1909).—Little, but good. A pretty Rose that comes easily, frequently and well. Not quite large enough, perhaps, to be a very useful Rose to the exhibitor. A Killarney-like Rose with rather more petals, not quite so vigorous a grower, and not so subject to mildew. It has been flowering all the season with me, and its plants are still carrying blooms, November though it is.

Marquise de Ganay (P. Guillot, 1910).—A large flower, silvery rose in colour, that has been frequently exhibited. It is a good grower, very free, and should be made a note of as one of the most promising of the Continental-raised Roses.

May Kenyon Slaney (Alex. Dickson and Sons, 1910).—To those who like variety in shape in their blooms, so that the whole box is not of the pointed persuasion, this Rose can be recommended. I had a fine large flower of it in a box of twelve at Southampton in June last. It is globular rather than pointed, pale blush pink on a cream ground that deepens with age, and in the autumn is very much deeper in colour. A good grower, not subject to mildew, and very free-flowering. Fragrant.

Mrs. Amy Hammond (S. McGredy and Son, 1911).—One of the very best all-round Roses of recent introduction. Grown for exhibition, it produces a magnificent flower; grown for garden decoration, it has all the points necessary for that purpose. Large flowers, borne on long footstalks,

HYBRID TEAS FOR EXHIBITION.

Lieutenant Chaure (Pernet-Ducher, 1910).—Another possible—hardly a probable—Rose to figure often in the exhibition box, and then only as a front-row flower. It did find its way into one or two boxes at the "National," but it was in the seventy-two and forty-eight classes, and it will very seldom be large enough to get into the twelves. It is a good colour, rather brighter than either of its parents, reported to be *Etoile de France* and *Liberty*. A believer in the hereditary tendency is not likely, therefore, to expect much from *Lieutenant Chaure*, but it was one of the twenty new Hybrid Teas selected by Mr. Mawley to be placed in order of merit. I believe I placed it at the bottom, or very near it, so that it is evident I do not think very highly of it for this purpose. It is a good garden Rose, however.

Mabel Drew (Alex. Dickson and Sons, 1911).—This Rose was also included in that list, but figured at the other end; in fact, I placed *Mabel Drew* second, George Dickson only beating it, and I shall be very much surprised if that is not the general opinion. It is a gold medal Rose, won at Salisbury in 1910, and has won for itself already a reputation that certainly entitles one to call it one of the best of the new Roses and one of the best

PLAN

PLAN OF SUNDIAL PEDESTAL AND BED FOR OLD-WORLD FLOWERS.

of noble proportions or for the embellishment of palatial surroundings, but is simply a quant and pretty idea that can be introduced into the tiniest cottage garden at little expense and with certain success. It is meant for those who love their gardens so much that they like to do things themselves, and as such is purely a "gardener's" sundial rather than a pretentious work of masonry ("sculpture" is, I believe, the word generally used). Just a few old bricks and thin roofing tiles, a short piece of iron pipe, two or three pieces of paving, and a little cement darkened by the addition of a little lampblack are all that is necessary; the joints should be quite dark. Round the centre plant a mixture of old-world plants, such as a pink Monthly Rose, two or three plants of Lavender, some Catmint, Thyme, and any old-fashioned odds and ends there is room for. If the sundial forms the terminal of a path between two borders, brick, on edge, paths are comfortable and dry, and when the joints are green with moss, grass, a dwarf Sedum, or creeping Thyme, are very

ELEVATION

(Scale of each illustration: Half an inch = one foot.)

very freely produced, in flower here from May to November. I do not know what place it will take in Mr. Mawley's Analysis, but I place it easily in the first half-dozen of the newer Roses. Those who have not got it should get it. A larger and taller Pharisæer with a peach (the rosarian's tint) flush that is not easy to describe. One cannot speak too highly of it. Vigorous, branching habit, very free-flowering and sweetly scented, it stands all weathers, and is as beautiful now in November as were its flowers in June. Messrs. McGredy have given us many beautiful Roses, and this is entitled to be called one of the best. It should be in every garden; certainly in every Rose garden.

Mrs. Arthur E. Coxhead (S. McGredy and Sons, 1910).—No Rose of recent introduction has found its way into so many gardens as this one, and the reason is not far to seek. I have never yet seen a split flower of Mrs. A. E. Coxhead. It always comes good. Notwithstanding the severe handicap of its bad colour, I expect to find it very high up in Mr. Mawley's list. I placed it third in order of merit. Those who say the new Roses have no scent should try Mrs. A. E. Coxhead, and then hang their heads with shame. It is particularly good in the autumn, too, and is a reliable Rose all through the season. If only the colour had been a little more pleasing! The raisers call it claret red, but there is no claret and very little red. I should call it a deep magenta puce, and the only time it has any pretence to good colour is under electric light. It bears the name of the wife of one of the keenest amateur rosarians that it has been my good fortune to meet, who, unfortunately, has to grow his Roses within the avenue radius of Charing Cross, but whose garden is a triumph over difficulties too numerous to mention.

Mrs. Andrew Carnegie (Cocker, 1913).—I have not grown this Rose, so can say nothing as to its behaviour; but I have had a great number of enquiries, to all of which I have given the same answer. I do not think an outdoor-grown flower has been staged in the South.

Mrs. Arthur Munt (Alex. Dickson and Sons, 1909).—An ivory tinted white flower of excellent shape, but not often large enough to stage. It is reliable, free-flowering, a fine autumnal variety, mildew-proof and scented, of Tea-like appearance and growth.

Mrs. Charles Custis Harrison (Alex. Dickson and Sons, 1910).—I mention this for its colour alone, a very warm, deep, almost crimson pink that lights up the spot it grows on in a wonderful fashion, and is very telling in the box if you can get it big enough. It is free-flowering, fragrant and a good grower, and a note should be made of it by those who like strong colours.

Mrs. Charles E. Allen (Hugh Dickson and Sons, 1911).—A very beautiful Rose, but not, I am afraid, large enough.

Mrs. Charles E. Pearson (S. McGredy and Sons, 1913).—To this I must say the same. I will refer to both of these varieties under the decorative Roses.

Mrs. Cornwallis-West (Alex. Dickson and Sons, 1911).—This is quite another matter. Here we have a magnificent exhibition variety. Easy to grow, easy to show and a very beautiful Rose, although it is not of the orthodox pointed shape with guard petals, but is globular, almost round.

FOLIAGE PLANTS PROPERLY ARRANGED BY AN ARTIFICIAL POOL IN A SURREY GARDEN.

The petals are of great substance. The colour is delicate ivory white, with a maiden's blush in the centre of the flower. Wants to be cut young before it shows the centre. It is a good grower, with free and branching habit, lovely foliage, not subject to mildew, very often with seven leaves instead of five. It has been well exhibited all through the season, and all exhibitors should get it if they have not tried it. It received the gold medal at Salisbury in 1910. Ought not this Rose to be named Lady Randolph Churchill?

Southampton.

HERBERT E. MOLYNFUX.

(To be continued.)

THE FLOWER GARDEN.

FOLIAGE PLANTS FOR THE WATER-SIDE.

THE accompanying illustration should, I think, serve to impress upon readers the beauty of certain well-known plants from the point of view of foliage. The Water Lily is *Nymphaea Marliacea alba*. Although no flowers happen to appear in the illustration, this Water Lily is, in my opinion, quite one of the best for all-round effect.

It gives each year during a lengthy period a great number of large and perfect blossoms, hard to excel for lustre and purity. It is often urged that this Water Lily is too large for small ponds. The remedy is simple. If the outer leaves are cut off, the crowded inner leaves will quickly fall flat to take their place. In the foreground of the illustration on the left is the common wild yellow flag, *Iris Pseudacorus*. It will be noticed what a magnificent foliage plant this *Iris* makes when grown actually in the water. In the background are *Iris sibirica* and its variety *Snow Queen*. The *Primula* growing upon the edge of the water is *P. japonica*, and is of a flaming vermilion colour. The tree in the background is *Prunus pissardii*, which I consider a faultless subject from every point of view—growth, foliage and flower. It would scarcely be believed at first sight that the pond is an artificial one, but such is the fact. Surely this method of construction is more beautiful than the unnatural arrangement which one commonly sees in gardens.

RAYMOND E. NEGUS.

Walton-on-Thames.

THE NAMING OF TULIPS.

It has required Mr. Jacob's "prod," as well as that of the Editor, to cause me to put pen to paper *re* the naming of Tulips, not because it was of no interest to me—it is of very great interest, as it must be to every large grower of Tulips. I do not think Mr. Jacob has any idea of the extent to which Tulips break in our soil, and the cause of the breaking is quite unknown to us. One large grower told me that he attributes it to poor cultivation; but we are quite sure that that is not the cause in our case. We have put eighty tons of raw cow-manure to the acre on Tulip land, and that cannot by any means be called poor culture; but the fact remains that nearly every variety of Cottage and Darwin Tulip that we cultivate has broken more or less. Sometimes the breaks do not amount to more than one or two bulbs per thousand, and in some seasons not that; but the season of 1912 gave us breaks in some varieties amounting to 30 per cent., and that is a serious matter to a market-grower, as the flowers of the broken forms have little market

value as cut flowers, however much they may be admired in the private garden. Many breaks are too ugly to be of any value at all, and are only fit to be thrown on the dust-heap, and that means a depletion of stock without any return. Many breaks are, however, in my estimation very beautiful, and bound to meet with favour as they become known. The process of propagation is slow, and it takes several years to make sufficient stock for sale.

Mr. Jacob speaks of the "break" as "the taking-on their final striped appearance"; but the stripe is not "the final take-on," as the stripes occasionally revert to self again, and it requires several years' selection to gain fixity. Again, the same variety frequently breaks into two distinct forms, and that seems to preclude Mr. Jacob's suggestion that a break should carry the name of the variety from which it comes. Clara Butt, for instance, gives two quite distinct breaks, and over twenty other Darwins have given two. Mr. Jacob surely would not like to see in a catalogue "Clara Butt Broken No. 1," "Clara Butt Broken No. 2"! It is the amateur, however, who has to be considered first in the matter of nomenclature, and to the uninitiated I think that to name all the breaks after the parent would lead to endless trouble and confusion; the fact of one name being connected with two varieties would mislead very many. If the name only applied to one or two sorts, it would not matter much; but the repetition of so many names would lead to confusion.

I agree with Mr. Jacob that growers should come to an agreement as to the naming of breaks, and if the trials at Wisley lead to uniformity of nomenclature, we shall be glad to have them. I think, however, it will be found that Krelage's breaks are totally distinct from those that have occurred in England. We have grown nearly all the Rembrandts that Krelage catalogues, but have not found one of them identical with our own breaks. It is unfortunate that the announcement of the trials at Wisley was made so late in the season, as all our stocks of breaks were already planted. I am, however, informed that the trials will be continued over a period of two or three years, and there will thus be an opportunity of arriving at some definite conclusions in due course, if all the growers are willing to send bulbs, which I urgently request them to do.

CHRYSANTHEMUMS IN TUBS.

WE are so accustomed to the cultivation of Chrysanthemums in pots for greenhouse and conservatory use that we are apt to overlook the value of early decorative varieties in the flower garden. A method which has much to commend it is that of growing Chrysanthemums in tubs, and when in flower to stand them out in the pleasure grounds and flower garden. It is surprising to see how one or two tubs laden with blooms will brighten up the surrounding landscape if suitably placed. In Gunnersbury House Gardens, Chrysanthemums in tubs are used with telling effect, as depicted in the accompanying illustration, in which two admirable tubs of the

white variety Parisiana are seen. Good cultivation is, of course, necessary to produce profusely-flowered specimen tubs. Three or four plants will suffice to fill out quite a large tub. The training of the plants requires much attention, and it is important that the lower branches should be trained at right angles to the tub, so that the blooms are produced uniformly almost to the ground-level. The value of Chrysanthemums in tubs in the pleasure grounds can hardly be over-estimated, producing as they do bright floral effects in the dull days of autumn, when deciduous trees are almost bare of leaves.

TREES AND SHRUBS.

THE WINTER PRUNING OF TREES AND SHRUBS.

ALTHOUGH a good deal of the pruning required by trees and shrubs is carried on during the

only likely to break prematurely into growth on those parts which will be cut away eventually in the ordinary course.

Overgrown Shrubberies.—Winter is the time to take such places in hand. Where a shrubbery has been planted early thickly to create an immediate effect, it is necessary to pay particular attention to pruning and thinning as soon as the plants touch each other, else, in the course of a few years, the majority will be spoiled. The best plan to adopt is to go carefully through the shrubbery and mark any plants that require moving bodily. Then decide whether all are worth keeping. In the event of a number being unsuitable for transplanting, cut them out and burn them at once. Then remove the remainder. The permanent plants may then receive attention, and a certain amount of regulating and thinning will be necessary. Whenever possible, branches should be removed bodily instead of being shortened, and on no account shorten branches in such a manner

CHRYSANTHEMUMS IN TUBS PLACED WITH GOOD EFFECT IN THE PLEASURE GROUNDS.

spring or summer, a certain amount may be done with profit during the winter months, especially when it applies to overgrown shrubberies and large-growing trees. The pruner must, of course, use his discretion when dealing with flowering trees and shrubs, for it would be out of the question to prune those during winter which blossom from the old wood, unless the pruning consisted of a little thinning of crowded branches; but those shrubs which bloom on the current year's wood, such as the summer-flowering Spiræas, Hypericums, Tamarix pentandra and Hydrangea paniculata, may be pruned towards the close of winter. Some people even prune these subjects before the end of the year, but it is not a good plan, for if a spell of very mild weather is experienced after the pruning, the buds begin to burst and the young shoots fall a prey to the first frost; whereas, in the event of the plants being left unpruned until February, young shoots are

as to leave an unnatural, globular outline to the shrubs. Such pruning is often noticeable in suburban gardens during late autumn and early winter. A sudden mania arises for cleaning up and pruning, and pruning frequently takes the form of clipping all loose growths of small trees and shrubs, so that they have a heavy, compact appearance. The writer has seen Thorns, Barberries, Diervillas, Privets, Mock Oranges and other subjects all treated in this way. Needless to say, there were no flowers the following year, and the owners of the plants wondered why. Evergreens which are to be transplanted may be pruned at this time, though any general pruning required by evergreens should be left until the spring.

Old Trees.—But it is large-growing trees rather than shrubs that offer work to the pruner at this time of the year. On every large estate and in almost every garden there are trees which contain

dead branches or show signs of decay, and such trees may well be taken in hand during the winter. Nothing detracts from the appearance of a garden so much as dead and dying branches about the trees, and numerous gardens which are otherwise well kept offer this defect. A couple of men with the necessary tools can make a considerable difference to the average garden in the course of a few weeks. One man, however, must be a good climber, for it is impossible to prune large trees from ladders. When such trees as Oaks, Elms and Sweet Chestnuts have become "stag-headed," or, in other words, their upper branches have died, they may often be rejuvenated by removing the dead parts to the highest living branchlets. Care must be taken, however, to preserve the natural outline of the tree during the work, and in some cases it may be necessary to remove a branch much lower than the highest living branchlet. Where there is danger of injuring anything beneath the tree by the fall of the branches, it will be necessary to sling the dead parts. This is done by securing a rope round the portion to be removed, and fastening the other end round the base of the trunk in such a manner that when the branch is cut away it will remain supported by the tightened rope resting in a fork between two of the upper branches. It may then be lowered to the ground without danger. Branches about other parts of the trees may be removed in a like manner, but they must be cut away eventually quite close to the bark. Very heavy branches may have to be removed in several pieces. All wounds so made must be dressed with coal-tar before leaving, otherwise they will form a resting-place for the spores of parasitic fungi.

Holes in trees may also be stopped during the winter. Scrape out as much of the dead wood as possible and cut away the margins of the holes until living wood is found. Paint the decayed parts with a strong solution of carbolic acid; then give a coat of tar and fill the holes with cement, or, if they are large, with deep cavities, with a mixture of bricks and cement. In some cases it may even be desirable to build up the cavities with a brick wall. In any case the work should be finished by a smooth cap of cement, which, when dry, may be tarred over or otherwise coloured to render it less conspicuous. Decayed patches of bark should be cut away to where living bark is found. The wood beneath should be scraped quite clean, and then be painted with carbolic acid, finishing off with a coat of tar. Fungous growths which appear on trees should be collected and burned as soon as they appear, for they are a source of danger to other trees. Trees from twenty to forty years old which are planted in the open often require a little attention, which can be given conveniently during the winter. The branch system often becomes too dense and

interferes with the upward development of the trees, or a number of leading shoots may appear to each tree instead of one vigorous leader. In such cases branches may be removed bodily close to the trunk, and rival leaders may either be cut clean out or be shortened. Lower branches of trees which are interfering with the free uses of lawns may be removed at this time also; but in carrying out this work care must be taken to leave the branches of different trees at varying distances from the ground, for, if all are removed to a general height, the effect will be anything but pleasing. It will thus be seen that any spare time which may occur during the winter may be profitably spent in work which will result in prolonging the

THE NEW CYPRIPEDIUM OLYMPUS. THE FLAT WHITE DORSAL IS $3\frac{1}{2}$ INCHES ACROSS.

life and increasing the beauty of trees, in addition to assisting in beautifying the garden. K.

NEW AND RARE PLANTS.

AWARDS OF MERIT.

Chrysanthemum Pink Pearl.—A very beautiful decorative variety with reflexing petals, and of a delightful pearl pink shade. A quite charming and useful addition by reason of colour alone. From Messrs. H. J. Jones, Limited, Lewisham.

Chrysanthemum Mme. Theresa Morel.—Large exhibition variety of the drooping type of Japanese. The colour is pale yellow.

Chrysanthemum Daily Mail.—A handsome, well-built—even if a little informal—curving Japanese variety. The florets are less formally imbricated than in some; hence the new-comer does not please those who would have every floret "so." Notwithstanding, it found many admirers, and gained its award of merit by an almost unanimous vote. The colour is rich yellow.

Chrysanthemum Golden Mensa.—The name is fully descriptive. Mensa, the pure white variety, represents, without doubt, the highest excellence to which the single-flowered Chrysanthemum has as yet attained. The one above named is a counterpart of the type, differing only in colour, which is of richest golden. It cannot fail to please.

Carnation Champion.—A very fine scarlet-flowered self, which, if not of the highest excellence and finish, is still a grand Carnation in some respects, particularly of colour and fragrance. The latter alone should make it popular. This and the three foregoing Chrysanthemums were exhibited by Messrs. W. Wells, Limited, Merstham, Surrey.

Carnation Gorgeous.—This fine American-raised sort promises to surpass all others of the Perpetual-flowering Carnations of the cerise-coloured set. In colour it is best described as a glowing cerise, with much less of the blue pigment than is seen in some. Its lighting-up attributes are remarkable. We know of no Carnation so distinctly brilliant and effective when under artificial light. From Messrs. Stuart Low and Co., Enfield.

Iris Vartani White Pearl.—A delightful and nearly pure white form of this early-flowering species. The pretty flowers are 4 inches to 5 inches high, and arise amid pointed leafage of nearly twice that height. The species is most probably closely allied to *I. reticulata*, and with the white form here given is well suited to the alpine-house. From Messrs. R. W. Wallace and Co., Colchester.

NEW ORCHIDS.

AWARDS OF MERIT.

Foremost among the new Orchids was *Cypripedium olympus*, from Lieutenant-Colonel Sir George Holford's wonderful collection at Tetbury, Gloucestershire. This is a massive flower of bold form, having a well-expanded white dorsal (see illustration) with a green base. From the same collection came the Westonbirt variety of *Odontoglossum crispum* Xanthotes. Other novelties to gain distinction were *Cypripedium Stella*, from Messrs. Sander and Sons; *Lelio-Cattleya Olenus* Blenheim Variety, sent by His Grace the Duke of Marlborough; *Sophras-Lelio-Cattleya Niobe*, from Messrs. Charlesworth and Co.; and *Cattleya andreaana* McBean's Variety, from Messrs. McBean and Co.

The foregoing novelties were granted awards by the Royal Horticultural Society on November 4.

GARDENING FOR BEGINNERS.

THE WINTER TREATMENT OF FLOWER BORDERS.

DURING the early autumn months there is much work of a seasonable character among herbaceous border plants that is better done at that time than at any other period of the year. This is true in spite of the fact that quite a large number of herbaceous plants are of a long-suffering nature, and submit to division and replanting at almost any time with impunity. In the autumn, however, when flowering has ceased, there is a general desire for tidying up, and at such times much useful work may be done. The cutting down of all plants may be proceeded with at once, taking care that in so doing labels are not disturbed, or even lost altogether. We grow these and other garden flowers chiefly for ornament or for their usefulness in a cut state.

Renovating the Border Soil.—

With the cutting down of the plants completed, it must be decided whether forking, digging, or manuring is necessary. Needless to say, the first and last of these will benefit both the border and the plants it contains. The addition of manure by its bulk alone lifts, lightens and aerates the soil, and in so doing performs important work quite apart from its enriching effects. The best manure to employ is that of a short, well-decayed nature. Failing this, Hop Manure is very desirable, and is capable of similarly good work. At such times, too, a free addition of lime may with decided gain be given to all soils of a heavy or water-holding nature.

Overgrown Plants.—Not a few of the best border plants are of so robust a nature that they quickly form mats of growth, which if left undisturbed will prove their own undoing in the near future. The digging up, dividing and replanting of such as these is, therefore, of importance at this time. The white perennial *Marguerites* (*Chrysanthemum maximum* and its varieties), *Michaelmas Daisies*, *Rudbeckias*, *Heleniums*, *Helianthus rigidus* in variety and *Achillea Ptarmica* are some of those that benefit by being divided and replanted each year. The varieties of the two groups first named quickly exhaust the soil, and manure should be added freely in such cases.

Change of Station.—One of the greatest aids to success in the case of soil-robbing or soil-exhausting subjects is to give a complete change of station or position. The one need be but a yard or two yards removed from the old position, there to find all the advantages which a change of soil brings in its train. The idea is simple in the extreme and its importance infinite, despite which it is rarely done. A much more frequent way is to lift a plant and, having dug and manured the ground, replant it in the old position. By these means a partial change of soil only is secured, while in that suggested above it is complete and entire.

Plant Selection and Discarding.—In the case of the more robust-growing, mat-forming subjects,

a considerable amount of plant material will have to be discarded. With not a few amateurs or beginners this goes very much against the grain, yet it has to be done if good results are to be obtained. The replanting of big clumps of things—*Trollius*, *Pyrethrum*, *Flag Iris* or *Michaelmas Daisy*—is a fallacy; the youthful plant is capable of much better work, and is commended to all. When replanting such as the white *Marguerites* or *Michaelmas Daisies*, only the strongest, outermost portions of the clumps—those that have developed with light and air all around—should be retained. The superiority of these compared with the innermost shoots of a plant will be obvious at a glance. Single growths, if well rooted, are the best, and, of these, six or a dozen arranged a few inches apart will not only form a goodly

covered with ashes (not too fine) or some similar material. Then, when the plants are placed in their winter quarters, they should be kept as dry as possible, consistent with safety. Until the frosty weather comes, air should be given night and day, so that the plants are kept in as dormant and hardy a state as possible. The lights, of course, should not be left off during rains; but when air is desirable, they may be tilted during the night. This will keep the plants in as good a condition as possible to withstand severe weather. When the time comes round in which frosts may reasonably be expected, the exposed sides of the frame should be banked up with some frost-resisting material, such as litter, Bracken, leaves, or anything in that way. It should be as dry as possible when put into its place, as dry material of any kind

A BORDER OF HARDY FLOWERS. MUCH WORK CAN NOW BE DONE TOWARDS OBTAINING A DISPLAY NEXT SUMMER.

group, but provide a display of the finest flowers in due season.

Plants Slow to Establish themselves, as, *e.g.*, *Peonies*, *Japanese Anemones*, *Day Lilies*, *Cimicifuga*, *Christmas Roses* and others, dislike—some even abhor—frequent root interference. Such as these should have the soil carefully forked about them, keeping at a respectful distance meanwhile, and a dressing of manure given. The *Japanese Anemones* may remain good for years with an annual mulching. *Delphiniums* or *Larkspurs* are good for three years without disturbance, a similar remark applying to the herbaceous *Phloxes*.

E. J.

TENDER PLANTS IN COLD FRAMES.

A GREAT many tender plants are safely wintered in cold frames, and, on the other hand, a good many perish therein. The greatest enemy to contend with is damp, and therefore precautions should be taken to combat it as far as possible. In the first place, the bottom of the frame should be above the surrounding ground, and the bottom

resists frost much better than when it is wet. In the event of severe and long-continued frost, the occupants of the frame may become frozen, despite the covering of litter. In this case nothing can be done, and the least harm will accrue if the plants are allowed to remain undisturbed. When the thaw comes is a very critical time, but with a little care the risk of injury may be greatly minimised. However pronounced the thaw, the frames should be allowed to remain shut up for twenty-four hours and the plants kept in absolute darkness. Then, at the expiration of that time, the lights must be tilted a little at the back, which is the highest part, in order to allow the moisture to escape, but not enough to admit daylight. They may be left in this way for two or three days, and after this the plants inured gradually to the light. Then, as soon as possible, the frame should be examined to ascertain the condition of its occupants, and also for the removal of any decaying leaves. In this way many tender plants may often be brought safely through a period of severe frost.

H. P.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Flower Garden.

Care of Plants in Frames.—Stock Geraniums that were lifted and potted when clearing the beds will have lost a good deal of foliage, and will be greatly benefited by a good pick over, cutting back any decaying shoots into the older wood. A little heat must be maintained to keep the plants growing quietly. By so doing, nice stocky cuttings should be ready for propagating early in the New Year.

Autumn-Rooted Cuttings of Zonal Pelargoniums will also be all the better for a good pick over, at the same time spacing the plants a little so that they keep in a stocky condition.

Marguerites that were put in during September or October have made considerable progress owing to the mild weather, and potting off should be done at once rather than let them become leggy through overcrowding. These may be kept in the cold frame, but water should be sparingly given, or the plants may suffer in the event of very severe frost.

Calecolarias, Veronicas and Antirrhinums are all rooted by now, and plenty of air should be admitted to the frames when the weather is at all open. Keep all decaying leaves picked off and the soil only moderately moist.

Echeverias and Sempervivums planted in frames must also be kept dry overhead, or there may be considerable decay of the under leaves. If this is noticed, a careful picking over will probably stop it, and if done now they should go through the winter nicely.

Coleus, Alternanthera, Iresine and Heliotrope must all be given a fair amount of heat to keep the roots active and the plants growing healthily during the dull days of winter; and to keep the plants stocky, give as much room between the pots as circumstances will allow.

Sweet Peas sown in the open air should now be 1 inch or 2 inches through the ground, and protection will be needed against birds and slugs. Netting and soot should prove effective. In exposed positions a few twigs on the windward side of the rows or clumps should protect them from wind and frost.

Seeds Sown in Pots the middle of October will also need attention, and now that the seedlings are nicely through the soil, all the air possible must be given to the frames. No half-hearted methods are admissible here. Take the lights right off during fine weather, and if mild and wet, put a 6-inch pot under each corner of the lights and thus admit all the air possible. Keep the soil in the pots as dry as possible, especially so in the case of the white and mauve varieties, which are acknowledged to be rather weaker than the other colours. With this kind of treatment it takes a good deal of frost to injure them, though it must be borne in mind that it is the sun after the frost that is more often the source of trouble.

Plants Under Glass.

Cinerarias.—The earliest batch may now be running up to flower, and should be given a small dressing or two of Clay's Fertilizer or some such mild manure. If they are required shortly, a little extra heat may be given, but it is inadvisable to overdo them in this respect. Later batches must be given more room as they require it, so as to keep the plants shapely and the foliage in a hardy condition. Fungus occasionally to keep down green fly; this is much easier and cleaner than spraying.

Primulas.—Early batches are now making a bright show, and to preserve the flowers in a good condition, a moderately dry atmosphere must be preserved. The Primulas like a damp bottom to stand on rather than a dry lattice staging. These, too, may be helped with a little manure; but it must be noted that plants at this season do not require as much feeding as plants growing freely in the summer months. Watering being less frequent, it does not get washed through the pots so quickly.

Lily of the Valley.—If bloom is wanted for Christmas, Berlin crowns must be put into heat at once; but the better practice is to secure retarded

crowns for blooming up to the end of January, when the non-retarded Dutch and Berlin crowns will force with much more certainty of getting good results. A few pots put in heat once a week should ensure a succession of flowers, and those who have not had experience of retarded crowns should note that a temperature of 55° to 60° is better than one much higher, the blooms being of better substance and lasting longer.

The Kitchen Garden.

Hot-Bed Material.—For very early Carrots and Lettuce, sowings should be made early in December or as soon after as possible, so that material for hot-beds should be prepared at once. Good, strawy litter, with a certain proportion of leaves, is the best for the purpose, and if it can be prepared by turning a few times under cover, so much the better. If too wet when it is finally made up into hot-beds and trodden well, it sometimes fails to heat, and the name is somewhat of an anomaly; and if too fresh, the heat rises very quickly and fails to last. So what should be aimed at is a bed that will give a fair amount of warmth over a long period, this being especially necessary at this season of the year, though, of course, a lining of fresh manure can be given to the frames when the heat is subsiding a little.

Fruits Under Glass.

Sulphide of Potassium for Peach Trees.—During a conversation with a large grower of Peaches for market, I was somewhat struck to find that the said grower rarely, if ever, syringed his trees during the growing season. I naturally asked how he kept down spider. "Quite easily," he said; "I dress or spray the trees two or three times during the winter and spring before they bloom with sulphide of potassium I presume at about half an ounce to the gallon of water, and this keeps them entirely free." I have no actual experience of this method of keeping down spider; but as the grower is a good man and not likely to make many mistakes, those who are troubled in this way might do worse than try what a dressing or two of sulphide would do if carefully applied during the winter months. I have used this for many subjects, and have never found it to injure them if carefully applied.

THOMAS STEVENSON

(Head-gardener to E. Mocatta, Esq.)

Woburn Place Gardens, Addlestone, Surrey.

FOR NORTHERN GARDENS.

The Flower Garden.

Mice Attacking Bulbs.—Spanish Irises, Tulips and Crocuses (especially the yellows) are very apt to be attacked by mice during the winter months, so a close watch should be kept on these marauders. I find Rodine a very effectual poison; it can be spread over pieces of buttered bread and placed under an inverted flower-pot slightly tilted up, so as to be out of the way of cats and dogs. Small spring traps of the "Gert" type also answer very well; these should be set about dusk and lifted early in the morning, or robins instead of mice are apt to be caught.

Sweet Pea Stakes.—There are now several types of these on the market, including wire columns, wire hurdles and collapsible hoop-and-net trainers. These are all excellent in their way, but for those who can procure them on their own property nothing is better than, nor, perhaps, quite so good as, natural stakes of Beech, Elm or Hazel branches. Now that the sap has gone down, these may be secured at any time, and be trimmed and pointed with a hedge bill.

The Rock Garden.

Cleaning Up Leaves.—The trees are now pretty well defoliated, and in many gardens, through the influence of the wind, many nooks and crannies of the rock garden have got a plentiful supply of them. In some cases, a few leaves around a subject of doubtful hardiness might do good. As a rule, however, the effect is detrimental; therefore they should be carefully cleaned away.

Stock in Frames.—Seedlings or rooted cuttings in frames should be frequently examined, to see that they are not suffering from lack of water, damp,

or the attacks of rats and mice. Give them abundance of air, but protect from the winter rains.

The Rose Garden.

Protecting Climbers.—As a result of the heavy losses among climbers last winter, suggestions have been made as to the means of preventing a recurrence of such heavy losses. Some of these suggestions (such as that of annual transplanting) are, I fear, impracticable. In the colder districts, however, something could be done. A light protection of Heather, Bracken, or Spruce or Yew twigs would in many cases carry the plants safely through the winter. In certain positions it might be well to untie all the shoots, then tie them loosely together in small bundles, lay them down on light supports, giving them a little protection with some of the materials indicated above; Broom or Wheat straw might also be used. Whatever system is pursued, however, air should be freely admitted among the shoots.

Plants Under Glass.

Chrysanthemums.—Although too early to commence propagation in earnest, yet, in the event of a scarce or shy variety showing a good cutting or two, they should be taken without hesitation.

Forcing Bulbs.—Hyacinths that are wanted in bloom at Christmas must now be afforded a temperature of from 55° to 60°, care being taken that they are not allowed to suffer for lack of water. Succession batches of bulbs should be brought on in a cool structure in rotation; better results are always obtained by gradual forcing than by forcing hard. What are being sold by some firms this season for the first time as "Prepared Hyacinths" are said to flower a month earlier than ordinary bulbs, the subsequent culture being the same.

Primula malacoides.—This attractive Primula is apt to give trouble through the flowers damping off. While it will not stand coddling, it should have a night temperature of from 45° to 50°, with a free circulation of air on all favourable occasions.

Fruits Under Glass.

Peaches.—The work of pruning, even in late houses, should now be brought to a close as soon as convenient. The trees should be as fully exposed to the air as circumstances will permit. The glass and woodwork should be thoroughly cleaned, mixing a little petroleum with the water used in washing. The trellises should then have a cloth steeped in neat petroleum drawn along them. The walls should be washed with hot lime and the trees be painted with Gishurst Compound or XL All Insecticide, after which they should be tied into position.

Early Vinery.—In a house where forcing was commenced at the beginning of the month, the night temperature should now be from 50° to 52°, with a rise of 5° during the day. The rods should be sprayed not later than 2 p.m.

The Hardy Fruit Garden.

Pruning Apples.—Where summer pinching has been done and the trees have been attended to in past years, with any necessary root-pruning or replanting, the work of pruning will be a comparatively easy matter, as fruit-buds will predominate. Still, the trees must be carefully gone over when there is no frost present, and the pinched shoots must be cut in to within an inch of the base. Old spurs which have become too long should also be cut in to one or two buds, and in training young trees, spurs should not be allowed to form nearer than 6 inches to each other.

The Vegetable Garden.

Rhubarb.—Where a dish of Rhubarb is wanted at Christmas, a few stools should now be introduced to heat. A temperature of 55° by night will be found suitable. Keep the stools dark and free from currents.

Seakale.—This crop can be mildly forced by the following method: Drive in stout wooden stakes, 30 inches high, at intervals along the rows; then run a light rail along the top of the stakes. Now cut a number of rough slabs of wood the requisite lengths, and lay them against the rail in a sloping position, forming an inverted V-shaped covering over the plants. When the requisite number of rows have been thus treated, fill up the intervening spaces with freshly-collected leaves.

CHARLES COMFORT.

Broomfield Gardens, Davidson's Mains, Midlothian.

NEW RULES FOR ENTERING DAFFODILS FOR AWARDS.

At the meeting of the Royal Horticultural Society on the 4th inst., the President and Council adopted the following new rules submitted by the Narcissus and Tulip committee of the society. The rules will take effect from January 1, 1914.

1. It must be clearly stated on the entrance form of any variety which is submitted to the committee for an award under which of the following heads the sender wishes it to be judged: (a) as a show flower, or "show"; (b) as suitable for garden decoration, or "garden"; (c) for growing and flowering in pots, or "pots"; (d) for cutting or market purposes, or "cutting"; (e) as a plant for rockwork, or "rockery." N.B.—Any one variety may be entered under more than one head.

2. The following conditions must be complied with in all cases: If submitted under (a), five stems with bloom are necessary for an award of merit, and twelve stems for a first-class certificate. If submitted under (b) and (d), for either award of merit or first-class certificate twenty-five stems must be submitted in two vases; twelve must be bunched and thirteen be loose. If submitted under (c) and (e), two pots or pans must be shown, each containing *not less than three bulbs*, for an award of merit. Four pots or pans, each containing *not less than three bulbs*, for a first-class certificate.

3. Official entrance forms will be provided, and may be obtained from the Royal Horticultural Society's Offices. One of these forms must be properly filled up by the exhibitor for each variety before it can be placed before the committee.

4. The words "show," "garden," "pots," "cutting" or "rockery" will in future be added to the usual award of merit or first-class certificate.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—*The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.*

FLOWER GARDEN.

PLANTING WATER LILIES (C. L. S.).—If you so wish, you may plant your Water Lilies either in tubs or pots, with every possibility of success. It is, however, necessary to turn them out of their receptacles every February, clean the pots or tubs well, and replant in new soil. Providing the tubs or pots were from 12 inches to 15 inches across and the same in depth, they would contain plenty of food material to keep the plants going for a year. Baskets will answer the same purpose, but there is danger of their rotting and allowing the soil to escape into the water.

TWELVE HERBACEOUS PLANTS (E. C.).—Had you given us the size of the border, we should have been in a far better position to advise you satisfactorily. However, here are some good things which should not be absent from any garden: *Aster Amellus*, *A. Beauty of Colwall*, *Aptulegia chrysantha*, *Campanula persicifolia alba grandiflora*, *Chelone barbata Torreyi*, *Delphinium Rev. E. Lascellei*, *Eriogon speciosus superbum*, *Eryngium*

amethystinum, *Gum Mrs. J. Bradshaw Gaillardia Lady Rolleston*, *Incarvillea Delavayi*, *Linum pedem. dalmaticum*, *Phlox Mrs. E. H. Jenkins*, *P. Baron Van Hedem*, *Pyrethrum Hamlet*, *P. Aphrodite* and *P. No Plus Ultra*.

TREATMENT OF BULBS OF LILIUM SULPHUREUM (G. W.). It would be a good plan to repot your bulbs of *Lilium sulphureum* now, as they would then root steadily throughout the winter. A mixture of loam, leaf-mould or peat will make a suitable compost for them. The loam should form two-thirds of the whole. During the winter they must be kept in a greenhouse or frame where they are safe from frost, and enough water should be given to keep the soil slightly moist, as in this way the roots are kept active. With the return of spring and increased growth, more water will, of course, be needed. In preparing the pots for the reception of the bulbs, effective drainage is very necessary.

FLOWERS FOR CUTTING (F. B. A.). The following plants will produce white flowers suitable for cutting. All may be planted now: *Phloxes* *Harry Veitch*, *Mrs. Forbes*, *Papilio Blanc* and *Sylphide*; *Lupinus arboreus* *Snow Queen*, *Desperis matronalis* (white variety), *Christmas Rose* (*Helleborus niger*), *Chrysanthemum Parthenium flore pleno*, *Achillea The Pearl*, *Anemone japonica*, *Snowdrops*, *Narcissi*, such as the *Poeticus* and *Tazetta* varieties, also the newer *Poeticus* forms; *Tulips* in variety, *Hyaacinthus Lilium speciosum album* and *L. longiflorum* varieties. Although not white-flowered, the Spanish and English Irises are very useful for cutting. You might also make sowings of *Sweet Peas*, and plant a few clumps of the red and white varieties of the *Everlasting Pea* (*Lathyrus latifolius*). These flowers will answer for church decoration.

TREATMENT OF GAZANIAS (G. W.).—You are somewhat late in interesting yourself in the wintering of *Gazanias*, as this is a matter that should have been taken in hand before now. Cuttings taken in August and placed in sandy soil in a close and shaded frame will root without any difficulty, and if, when potted off, they are kept in a light and airy structure, no trouble will be experienced in keeping them through the winter. Even now, provided you have a snug little structure kept at a temperature of 50° to 60°, a fair percentage of cuttings may be struck. They should be shaded from the brightest sun, and care must be taken not to overwater them. The old plants may also be lifted and potted or laid in boxes and placed in a good, light position in the greenhouse. Before potting, straggling roots and shoots should be shortened back in order to economise space, leaving as many as possible of the shoots near the centre of the plant.

PLANTING EREMURUS (M. A.).—You will find that the species of *Eremurus* will prove more satisfactory if grown in a border with other plants than if planted on a lawn, for, except when in bloom, the various kinds are not very ornamental, and the leaves become decidedly untidy towards the middle of summer. At the same time, they must not be planted in places where the roots are likely to be damaged by digging holes for other plants. They usually give satisfactory results when planted among low shrubs where sufficient space has been left between the shrubs to allow of the proper development of the leaves. Do not plant entirely in leaf-mould. Provide good loamy soil and dig some leaf-mould among it. The soil should be at least 12 inches to 15 inches deep. If a clump of *Eremurus* plants is formed, Lilies may be planted between, providing the former are not very close together. The evergreen shrub is *Coronilla glauca*.

BEE FLOWERS (F. B. A.).—The flowering shrub to which you refer is apparently *Buddleia globosa*, although we have not previously heard it called by the name of the "Honey Ball Tree." It is a great favourite with bees. The following plants are all appreciated by bees: *Arabis alba*, *Wallflower*, *Heather*, *Clover*, *Lime*, *Lavender*, *Buddleia variabilis* varieties *veitchiana* and *magnifica*, and *Michaelmas Daisies*. The *Arabis* is excellent for planting near hives on account of its early flowers in spring. Bees collect a great deal of pollen from its flowers. Likewise the *Michaelmas Daisies* are valuable for autumn. Your garden soil may be improved by trenching it 2 feet to 2½ feet deep, and adding grit, long horse-manure and burnt clay to the subsoil. When trenching, be careful that you do not bury the surface soil. Keep that to the top all the while, but thoroughly loosen the lower soil and incorporate the manure and other materials with it. Well-rotted manure should be used for the surface soil. If the soil is deficient in lime, the shortage may be made good while the work is in progress. The following evergreen trees and shrubs are likely to serve your purpose: *Pinus insignis*, *P. Pinaster*, *Cupressus macrocarpa*, *C. lawsoniana*, *Thuja plicata* and *Quercus ilex* among trees; and *Berberis stenophylla*, *B. Darwinii*, *Escallonia macrantha*, *Rhododendrons* in variety, *Elaeagnus pumilus variegata*, *E. macrophylla* and *Choisya ternata* among shrubs.

LAYING OUT A GARDEN (Amateur).—The first thing to do with a garden as long neglected as the one you refer to is to rid it of all superfluous material—weeds, useless, overgrown or decaying shrubs—and make a bonfire of them on the spot. If the grass with which you say the garden is overrun is one of the common meadow grasses, it will be easily got rid of by cutting down and burning the tops, and by subsequently trenching in the roots. It, however, it should prove to be the Couch Grass, with long, whitish roots spreading underground, nothing short of forking the whole area and picking it out will suffice. This work needs to be carefully done, since every scrap of root is capable of making a new plant. With a clearance thus made you will be able to discover any pathways, should such exist, since the garden may be made to conform to them in some measure. If no paths exist and you have a clear course before you, we suggest you lay the garden out as follows: We will assume that the house is at its southern end, and that there is a side

entrance to it. In such case trellis off at the back a space of 12 feet, arranging a border 3 feet or 4 feet wide in front of the trellis, to be presently planted with *Roses*, *Carnations*, or what you will. The trellis also should be planted with climbing *Roses*. In front of the border a path 4 feet wide should be made. On either side, borders 3 feet wide for hardy herbaceous plants should be formed, with paths not less than 3 feet wide in front. The central portion, to about half the length of the ground, might be laid down in grass, with flower-beds at the four corners. Beyond this, a vegetable garden plot—it may be made large or small, as fits your requirements—to be shut out from view by a lattice wood screen or by a hedge of *Yew*, *Holly* or *Privet*. If you are fond of fruit, four bush pyramidal *Apples*, one at each corner—should be planted. The paths in this section need not be quite so spacious as those in the flower garden portion, but for convenience should encompass the plot after the fashion of the flower garden. In such case the side borders could be devoted to the raising of *Lettuce*, *Radish*, *Spinach*, *Carrots*, *Shallots*, *Onions*, together with *Mint*, *Thyme*, *Parsley* and other useful things, while the larger central plot could be devoted to border-growing subjects. Needless to say, the soil of a garden so long neglected will require deep cultivation, with heavy manuring in all parts save that set aside for the lawn. You say nothing of the character of the soil, so that we cannot help you more definitely. Dry paths in all gardens are very desirable, hence you had better excavate the soil to about a foot deep, filling in first with clinkers and rough ashes, and finally with fine ashes or gravel for the surface. The excavated soil from the pathways should be turned on the border portions to increase their depth and save labour in cutting elsewhere. When this is done, the rough clinkers may be introduced, leaving the surface covering for the paths till the last. As you say you know nothing of the work, it would be advisable to obtain the assistance of a practical gardener.

THE GREENHOUSE.

OLEA FRAGRANS (H. E. B.).—The plant concerning which you enquire is undoubtedly *Olea fragrans*, a native of China, whence it was introduced as long ago as 1771. The flowers, though small, are deliciously fragrant. It is fairly hardy in the South of England, and should prove quite so with the protection of a wall. At one time it was more grown as a conservatory or greenhouse plant than it is now, its ornamental leafage and sweet-scented flowers being its greatest recommendation. So fragrant are the blossoms that a single plant will make its presence known in a good-sized structure. Besides the ordinary form with white flowers there is one sometimes met with in Italian gardens, in which the blossoms are of a yellowish-buff tint.

ARUM LILIES FLOWERING TOO SOON (T. S.).—You can do nothing to prevent your *Arum Lilies* from flowering now, as the scapes are quite ready for pushing up and will naturally do so. You could not do more than you have done to keep them back. The best thing to do will be to cut the flowers off now as they appear, and keep them in a comparatively quiet state till after Christmas. Then encourage them to grow by a little additional warmth, and an occasional stimulant if the pots are well furnished with roots. By this means you will have flowers at Easter, but, of course, forethought must be exercised in that respect, as the development of the blossoms largely depends upon the weather and other particulars which it is impossible to foresee. Thus, as Easter approaches, if the flowers are likely to be too early, keep them cooler, while, if backward, give them a little additional heat.

TO TURN HYDRANGEAS BLUE (J. A.).—Various prescriptions for turning *Hydrangeas* blue have at one time or another been published, but invariably with success. The most effective that have come under our notice are two preparations the composition of which is kept secret, namely, *Azure* and *Cyanol*. The first named (*Azure*) is a speciality of Messrs. William Cutbush and Son, Highgate. They have, during the present season, shown numerous examples of *Hydrangeas* whose flowers had been changed to blue by the use of *Azure*, notably a fine lot at the spring show of the Royal Horticultural Society at Chelsea. The other preparation (*Cyanol*) is, we believe, from the Continent. It can be obtained from Messrs. William Wood and Sons, horticultural sundriesmen, Wood Green, London, N. Our experience is that the presence of lime in the soil is greatly against the production of blue flowers, and this is borne out by the instructions for the use of *Cyanol*, viz., the water and soil must be free from chalk. Rain-water is preferable. No artificial manure must be applied.

MISCELLANEOUS.

THE HICKORY BEETLE (W. G.).—The insects found in the Hickory wood are the larvae of the Hickory beetle, an insect which sometimes causes a good deal of annoyance in the United States. It is not a native of the British Isles, but there are other beetles here which act in a similar way. The dark-coloured excavation is not likely to have been caused by the goat moth, but it is not possible to suggest which insect has made it.

TREATMENT OF LAWNS (F. H. C.).—The most satisfactory way to clear a lawn of weeds is to encourage the grass to outgrow them; for after a lawn has once become thoroughly weedy, it is a hopeless matter to try to eradicate the weeds unless the grass is made to assist by feeding it liberally. Where coarse grasses exist, it is a good plan to provide a dressing of sea sand at the rate of two cubic yards to the acre, but where the grasses are fairly fine but patchy, it is better to apply good soil free from weed seeds, well-rotted farmyard manure or bone-meal. Soil may be applied to a depth of half an inch, keeping it

raked about well until it disappears. Farmyard manure may be used at the rate of four or five tons to the acre, according to the condition of the grass, and bone-meal may be given at the rate of half a ton to two acres. Good works on lawn grasses are published by Messrs. James Carter, Raynes Park, S. W., and Messrs. Sutton and Sons, seedsmen, Reading. If you wish to remake your Yarrow lawn, it is possible to procure Yarrow seed in quantity from various firms of seedsmen.

FLANNEL WEED IN PONDS (C. B.).—The material recommended for destroying Flannel Weed in ponds was copper sulphate used in the proportion of one part of copper sulphate to 750,000 to 1,000,000 parts of water. The chemical should be placed in a canvas bag and be drawn through the water until dissolved. It is usually necessary to apply the copper sulphate two or three times between April and October.

FUNGUS MYCELIUM IN GROUND (Arminius).—The fungus mycelium in your garden can be destroyed by digging a trench round the affected area deeper than the mycelium penetrates; then digging unslaked lime into the affected ground. A little fungus may appear again next year, but a second application of lime should prove effective. Fungus mycelium may also be killed by soaking the ground with a strong solution of sulphate of iron.

NAMES OF FRUIT.—*R. Y.*—Boston Bisset and Marie Louise d'Ucle. —*J. Y. N.*—1, Potts' Seedling; 2, King of the Pippins; 3, Hawthornden; 4, Stirling Castle; 5, Lady Heniker. —*Saxiflora*.—Large fruit, King Harry; small, Winter Peach. —*Miss S. Limes*.—1, American Mother; 2, John Apple; 3, Ribston Pippin; 4, Adam's Pearmain; 5, Cellini Pippin. —*W. H. N.*—Ribston Pippin.

NAMES OF PLANTS.—*K. M. R.*—Probably a dyed flower of *Anaphalis margaritacea*. —*H. P. E.*—*Asclepias curassavica*; 2, *Elaeagnus pumilus aurea*. —*Parley*.—*Poterium tenuifolium*. —*Enquirer*.—1, *Oxalis acetosella*; 2, *Sedum rupestre*; 3, *Saxifraga aizoon*; 4, *Potentilla species*, cannot name without flowers; 5, *Polemonium caeruleum variegatum*; 6, *Lychnis Viscaria*; 7, *Sempervivum Funckii*; 8, *Saxifraga Hostii*; 9, *Veronica speciosa* variety; 10, *Saxifraga aizoon* variety. —*W. P. Stanton*.—1, *Nephtolopsis cordifolia*; 2, *Chrysanthemum*, garden seedling; 3, *Amblyon* species, cannot name without flowers.

SOCIETIES.

SCOTTISH HORTICULTURAL ASSOCIATION.

THE monthly meeting of the Scottish Horticultural Association was held in the Hall, 5, St. Andrew Square, Edinburgh, on the evening of November 4. Mr. David King, Osborne Nurseries, president of the association, occupied the chair. The exhibits before the meeting were of some interest, and consisted mainly of Chrysanthemums. Mr. W. G. Pirie, gardener to C. W. Cowan, Esq., Dalhousie Castle, exhibiting four single varieties, for which a cultural certificate was awarded. These were Miss B. M. Cowan, Miss Colquhoun, Weston Gem and Coddie White. Mr. R. H. Cockburn, gardener to Sir C. W. Cayzer, Gartmore House, Perthshire, exhibited a new single Chrysanthemum, Lady Cayzer. Potato Irish Gem, from Mr. W. H. Sands, Hillsborough, County Down, Ireland, was awarded a cultural certificate, and a new wasp and fly trap, invented by Mr. Thomas Reid, Eildon Hall Gardens, Roxburghshire, was recognised by the inventor being highly commended for the trap. The lecture of the evening was given by Dr. W. G. Smith of the Edinburgh and East of Scotland College of Agriculture, and proved one of deep interest and high value. It was well illustrated with limelight illustrations. The subject was "The Influence of Drought on Plant Form." Dr. Smith made an exceedingly able presentation of his subject, discussing it with a wealth of illustration and giving many examples to support the position maintained. The influences of various soils, &c., formed an interesting section, while the effect of experiments on plants cultivated away from their usual conditions was also shown. The whole lecture was full of value for the student of plant life and for horticulturists in connection with their work. Dr. Smith was heartily thanked.

BIRMINGHAM AND DISTRICT GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION.

A SHORT, concise, but practical and comprehensive paper on "The Winter Dressing of Fruit Trees" was read to an assembly of the members of the above society by Mr. R. T. Parker, gardener to Mrs. Lacey, Westbourne Road, Edgbaston, on the 2nd inst. When introducing the subject in so short a paper, he stated that it was his idea to stimulate a discussion that evening which he hoped would result in practical future application. Primarily, uncleanliness was the reason why so many fruit trees and bushes afforded a refuge for insect pests and other germs that are the origin of so many disastrous diseases in the majority of fruits. Therefore, if the grower wished to ensure himself against the loss of valuable fruit, the most effective course was for him to adopt a systematic annual cleansing of his trees. In the snug seclusion of the crevices of the bark around the trees, the insects and their larvae are secreted, and it is only by persistent application of the respective washes that it is possible to prevent them from attaining maturity. The lecturer clearly demonstrated this in his allusion to the American blight (or aphid), which he had abolished from his trees by the use of a wash compounded from carbonate potash, caustic soda and soft soap, dissolved in water. As this solution is liable to burn the skin of the

applicant's hands, if any falls upon them, he usually wears a pair of rubber gloves for protection, and applies it with a knapsack sprayer. Different insects, he said, required different treatment owing to the fact that there are two classes of insect pests—the sucking and the biting. Occasionally the biting insects would survive a wash which, if used too strongly, might permanently injure the particular tree. For the former class of pests, Paris green, a poison, dissolved in water, would be found to be of advantage if used discreetly. Also London purple, a waste material from dyeworks, furnished an economic destroyer of the winter moth caterpillar. Arsenate of lead, too, made a good spray for the biting pests and fungi. Much, he urged, could be done to forward the growth of trees by the use of chemical manures, such as a dressing of basic slag or potash for Black, Red or White Currant trees, while nothing assisted trees of ten to twenty years' standing better than animal manure—especially that obtained from the poultry farm. Although the ensuing discussion was not at first as keen as it might have been, several important points were eventually raised, and these the lecturer replied to in a manner which proved that he was thoroughly conversant with his subject. After the usual vote of thanks the meeting terminated.

CHRYSANTHEMUM CONGRESS AT GHENT.

THE members of the French Chrysanthemum Society held their 1913 Congress at Ghent in connection with the Autumn Show held there from the 25th to the 28th ult. The programme was a full one and included, besides the meeting of the congress, several days' festivities, which were much enjoyed. At the congress meeting M. Yger presided. He was supported on the platform by a bureau composed of the following gentlemen: M. Vermeire (the representative of the Belgian Government), M. F. Couillard, M. Rabbe, M. Ph. Rivore (secretary), M. Firmin de Smet, M. Rozamboncharlat, M. A. Galber (president of the Ghent Society), M. Duboulet and Mr. Harman Payne (representing the National Chrysanthemum Society). A paper was read by Dr. Chiffolle of Lyons on insect pests, after which a discussion ensued, in which M. H. Crepin, M. Clement and the president joined, and it was resolved that a new edition of the work published by the society some years ago on insect pests and diseases of the Chrysanthemum should be issued shortly. Another paper by M. Godde on the influence of magnesium salts on Chrysanthemums was read and discussed. M. Couillard dealt with the question of a revised classification. Another chemical question was also considered, viz., the effect of sulphur and sulphur compounds on the vegetation of the Chrysanthemum. The congress medal annually awarded was unanimously voted to Dr. Chiffolle; M. Couillard was promoted to the rank of Officer du Mérite Agricole; and M. Firmin de Smet was awarded the gold medal of the society in recognition of his hospitality in receiving the society. It was arranged that the next congress should be held at Malm in 1914.

On the Sunday evening the members were entertained by the Royal Agricultural and Botanical Society of Ghent at a reception held in the Casino. They were also provided with special tickets to view the closing ceremony and distribution of prizes by the King of the Belgians. They were likewise invited to a day's outing at Bruges to see the sights of the town and the large nursery of Messrs. Sander and Sons there, and also to a luncheon given by M. Firmin de Smet. Quite a large party, including all the English visitors, accepted. M. Couillard returned thanks on behalf of the French Chrysanthemum Society, and Mr. Harman Payne, opening his speech with a humorous quotation from Molière, which delighted his audience, replied for the English visitors.

CHELMSFORD GARDENERS' ASSOCIATION.

THE third meeting of the winter session was held on the 31st ult. at the County Laboratories. Mr. C. Wakely presided over about fifty members. Mr. Jackson of Braxted Park gave an interesting and practical lecture on "Begonias." The lecturer commenced by pointing out the value of Begonias for decoration, especially the winter-flowering ones. Mr. Jackson divided his lecture into several parts, and dealt with the varieties of Begonias in the order named—*Begonia Gloire de Lorraine*, winter-flowering; *Begonia*, tuberous-rooted; *Begonia* and fibrous-rooted *Begonia*. Each variety was dealt with in turn, and the cultivation and propagation explained in a very practical manner. Other subjects, such as staking, watering, potting and insect pests, were also dealt with. A vote of thanks was accorded Mr. Jackson at the close.

ROMFORD HORTICULTURAL AND CHRYSANTHEMUM SOCIETY.

THE annual exhibition in connection with the above old-established society was held in the Corn Exchange, Romford, on Thursday, the 6th inst. There was a very fine display of Chrysanthemums and other flowers, and, owing to the committee having largely substituted vases for the old-fashioned boards, the effect was very charming. Sir Montague Turner, president for the current year, was a very successful exhibitor, his gardener, Mr. Humphreys, staging some particularly good cut blooms and specimen plants. Among the former was the best bloom shown in the open section, the best in the amateur's division being shown by Mr. Bishop of Brentwood. The Rev. E. M. Bell (gardener, Mr. Gilbert) also showed some very fine cut blooms and a particularly good specimen plant. Other successful exhibitors of Chrysanthemums were Messrs. Sewell and Page. Fruit was surprisingly good, dessert Apples being shown in large quantities. Vegetable exhibits, though not so numerous as usual, were of fine quality and well displayed.

NATIONAL CHRYSANTHEMUM SOCIETY.

SELDOM, if ever, have Chrysanthemums of better quality been shown than those at the Crystal Palace on November 5, 6 and 7. The Japanese varieties were quite up to the high standard of previous years, and it was particularly pleasing to notice the unusual number of incurved varieties that were given a prominent position in many groups, in addition to the dressed blooms shown in boxes. Probably no section has made more rapid strides than the singles, and, incidentally, it might be mentioned that some of the leading judges are a little hazy as to what constitutes a single. That there should be no misunderstanding in the near future, it is imperative that the National Chrysanthemum Society should lay down a very clear and definite rule upon this point. The wonderful improvement that has been wrought among decorative varieties is also noteworthy, and the large group of market, decorative and single varieties staged by Messrs. Craig, Harrison and Craig of Heston near Hounslow was undoubtedly one of the features of the show, more particularly as most of the varieties were of this firm's raising. The magnificent groups by Mr. Norman Davis and Messrs. W. Wells and Co. were deserving of the highest praise, and the large gold medal offered by Messrs. Clay and Son for the best miscellaneous exhibit in the show was awarded to the former. The leading prize-winners were as follows:

COMPETITIVE CLASSES.

The class for a floral display of Chrysanthemums and suitable foliage plants in pots (trade excluded) was won by J. C. Eno, Esq., Wood Hall, Dulwich, with a large circular group that did full justice to Mr. R. B. Leech, the able head-gardener. The arrangement was very artistic. Exhibition, decorative, single and Pompon varieties were pleasingly associated with the ornamental foliage of *Crotons*, *Brazeans* and *Asparagus*. Moreover, the quality of the blooms left little to be desired. Bob Pulling was shown in great form, while Mensa, the choicest of all singles, was seen in the height of perfection. Lady Tate, Park Hill, Stratham Common (gardener, Mr. W. Howe), was second. This exhibit contained blooms and foliage plants of good quality, but we could not help thinking that the exhibit suffered from overwatering.

There was strong competition in the class for twelve vases of Japanese blooms, the first prize going to Mr. A. Chandler, gardener to Arthur James, Esq., Rusby. Among the best blooms were W. Turner, Reginald Vallis, His Majesty (a rich crimson, shown in remarkably good form), Thomas Lunt and Mrs. Gilbert Drabble. Second, the Marquis of Lute; third, Mr. Philip Ladds.

In the class for cut blooms, open to affiliated societies, the challenge trophy was awarded to the Finchley Chrysanthemum Society for an exhibit which commanded general admiration.

Considerable interest was centred in Class 5, for forty-eight Japanese blooms. The first prize, including the Holmes Memorial Challenge Cup, fell to the lot of Mr. A. Chandler, gardener to Arthur James, Esq., Coton House, Rusby. It was a grand collection, slightly under-sized, but of good quality and very refined. Of the blooms shown, the following were remarkably good: Lady Talbot, W. Turner, Marie Loomes, His Majesty, Mrs. Drabble, Thomas Lunt and Mrs. F. C. Stoop. Mr. Stevenson, gardener to E. G. Moeat, Esq., Woburn Place, Addlestone, Surrey, was second with a weighty set of blooms which were a shade too coarse; third, Mr. G. Hunt, gardener to Pantia Ralli, Esq., Ashlead Park, Epsom.

It was pleasant to see four really fine exhibits in the class for thirty-six incurved blooms. The first prize and challenge cup were won by Mr. G. Hunt with a faultless set. His best blooms included Clara Wells, Mrs. P. N. Wiseman, Pantia Ralli, Duchess of Fife and Mrs. F. Judson. Mr. H. R. Farmer, gardener to the Marquis of Bute, was a capital second, followed by Mr. F. J. Brown, gardener to Miss Langworthy, Gays House, Holyport.

Mr. H. R. Farmer, Carlisle, was successful in the class for twelve incurved blooms. His best blooms included G. F. Evans, Clara Wells and Mrs. F. Judson. Second, Pantia Ralli, Esq.; third, Miss Langworthy.

Sir Albert Rollit (president) offered a cup for twenty-four Japanese blooms, and this was won by Lord Foley (gardener, Mr. H. C. Gardener). There was excellent competition, there being ten first-rate exhibits, which created a wonderful display of colour. The somewhat uncommon shades of colour in varieties such as Rose Pockett, Amber Queen, Francis Jolliffe and Master James contained on the winning board call for special mention.

MISCELLANEOUS EXHIBITS.

As usual, these were of exceptional interest, and, together with the displays in the competitive classes, made up an exhibition that reminded us of the days when the Chrysanthemum was at the zenith of its popularity.

Mr. Norman Davis, Framfield, Sussex, set up a large and beautiful exhibit of great artistic merit, representing Japanese, incurved and single Chrysanthemums in superb form and condition. Vases and stands were utilised to display the flowers, and by the aid of choice foliage plants a noteworthy display was made, that won a large gold medal, and Messrs. Clay and Son's gold medal for the best miscellaneous exhibit in the show. This exhibit was set up in front of the Royal Box in the Central Transept, and occupied the whole front.

Messrs. W. Wells and Co. Limited, Mersham, Surrey, also won a large gold medal for a very large and comprehensive group of cut Chrysanthemums, set up in most attractive fashion, and which was admired by crowds of sightseers. Masses of Japanese Queen Mary, Mrs. Gilbert Drabble, Daily Mail and other new and choice Japanese varieties, and a host of beautiful singles and decorative sorts, made a beautiful display of a comprehensive character.

EDITORIAL NOTICES.

Every department of horticulture is represented in **THE GARDEN**, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

*The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in **THE GARDEN** will alone be recognised as acceptance.*

Offices: 20, Tavistock Street, Covent Garden, W.C.

NOTES OF THE WEEK.

The Scarlet Oak.—During the past few weeks the Scarlet Oak has been very beautiful. Its large leaves assumed a brilliancy of colour not found in those of any other kind of tree growing to as large a size. The first specimen that attracted our attention was growing near the bottom of a high railway embankment, where the roots had a deep, friable loam to grow in.

Protecting Early-Flowering Chrysanthemums.—Now that these plants are over, they should be trimmed up, and those varieties which are required for cuttings lifted and placed in a cold frame, bedding them in leaf-soil, as only a few of the hardiest can be relied upon to stand the winter outside without some protection. By protecting them as advised, much better cuttings can be obtained.

Protecting Ferns with Leaves.—When the leaves are being collected, it will be found a good plan to place some among the outdoor Ferns. It acts as a protection for the choicer and more tender kinds, as well as a mulching, from which the Ferns, bulbs and other plants growing among them will benefit. The leaves should be carefully worked among the plants with the hands, when they will soon get settled down and be quite hidden by the new fronds in the spring.

Rosemary and Carnations.—A few days ago we were short of foliage to arrange with some perpetual or winter-flowering Carnations, and toll was taken of the Rosemary bush that nestles by the front door. Two or three good, erect shoots were thrust carelessly into the centre of an old Cornish pitcher that had been loosely filled with Carnations, and the effect was as pleasing as the combination was fragrant. No doubt sprays of Rosemary might be effectively arranged with other kinds of flowers at this season.

Transplanting Montbretias.—Where these have become too thick, they should be taken up now and divided, selecting the strongest bulbs for replanting. When they are to occupy the same ground, it should be well trenched and manured. This useful ornamental plant is often neglected and allowed to become overcrowded, which results in weak growths and few flowers. If the plants are not lifted, it is not wise to remove the dead foliage, as this protects the young, tender shoots, which are so easily damaged by the cold winds.

Proposed Plant Collector for Wisley.—On another page we reprint a long letter that appeared in *Country Life* of last week. The writer of the letter, who is an enthusiastic Fellow of the society, suggests, among other things, that the Council should appoint a plant collector, whose duty it would be to visit foreign countries for the purpose of collecting new or rare plants which could be grown at Wisley. We have reason to believe that some members of the Council have had the

subject under consideration for some time. There is a good deal to be said for and against the idea, but it would seem that a wealthy society such as the Royal Horticultural Society now is could with advantage devote some of its surplus funds to such a purpose.

Austrian Heir-Apparent at Kew.—Those who have heard of the Archduke Francis Ferdinand's interest in horticulture will not be surprised to know that on Sunday last, the day after his arrival in London, a visit was paid to our national garden at Kew. In private life the Archduke takes a keen interest in all that pertains to his own garden. He is said to have largely superintended the laying out and planting of the grounds surrounding Konopischt, his residence in Bohemia.

Lettuces for Winter Use.—Plants growing in the open at this time of the year are more tender and more easily damaged than in the summer-owing, undoubtedly, to the dull weather and short days. If a frame-light can be placed over them, it will be found of great advantage; or plants may be lifted carefully and placed in a frame, taking care not to damage the leaves. Seeds of the Cos varieties may be sown thinly at intervals in boxes or pans and placed in a temperature of about 55° or 60°. The plants will be very valuable for salad during the winter when cut in a young state.

Mid-November Roses.—On looking over the Roses on Monday last, the 17th inst., we were surprised to find quite a number in full bloom. The following list of varieties that were carrying really good flowers may be of interest: La France, Lady Battersea, Lady Pirrie, Frances Charteris Seton, Grüss on Teplitz, Gloire de Dijon, Miss Cynthia Forde, Betty, Nita Weldon, Mme. Ravary Rayon d'Or, Pharisäer, Margaret Molyneux, Mrs. Alfred Tate, Richmond, Lady Alice Stanley, Mrs. A. Mun, Sunburst, Earl of Warwick, Königin Carola, Gustav Grunerwald, Mrs. Herbert Stevens, Orleans, Jessie and Hiawatha. The last named is a weeping standard budded on *Rugosa* stock, and has been continually flowering since the end of July. Jessie is as bright and full of bloom as in the summer, and Orleans is nearly as good.

Guelder Rose and Traveller's Joy.—These two native plants are very beautiful objects of the country-side at this season. The former, by virtue of its autumnal tints, serves to brighten up many a hedgerow and copse with its brightly-coloured leafage. Everyone is familiar with the Traveller's Joy (*Clematis Vitalba*), which at this season is especially noticeable on account of its feathery fruits, which have earned for it the name of Old Man's Beard. This subject is often seen clothing trees or rambling over farm buildings. It is singular that it is usually found near to, or associated with, places of habitation, often marking the approach to a village, and this possibly explains the meaning of its name Traveller's Joy.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

The Almond in Scotland.—The Almond is hardly enough to grow, to flower and to fruit in at least the milder districts of Scotland. The tree succeeds here and occasionally bears abundant crops.—R. P. BROTHERSTON, *Tynninghame, Prestonkirk.*

Rose Peace.—In reply to "Pax," page 559, issue November 8, I beg to say that I do refer to the Tea-scented variety. It has long, pointed buds, the petals being of a pale lemon colour under glass, deeper in the open. I have found this variety very impatient of drip from trees and from buildings; it does not thrive well in very moist soil. Under glass, either in pots or borders, the plants succeed and blossom over a long period.

Prizes for Front Gardens.—I am quite sure that "Marguerite," page 558, issue November 8, will soon see a change for the better if she offers prizes for the best front gardens in the village in which she lives. I have had some considerable experience in the matter of framing rules in such circumstances and in judging the gardens. I do not intend to go into detail here, but would suggest that "Marguerite" takes into consideration the sizes of the gardens, as, if there is a wide margin, it would be more satisfactory to divide them, say, gardens of so many square yards and over, and gardens under the size decided upon. Then the owners of the two classes would compete against each other respectively. The largest gardens are not always the most beautiful, but it is a fact that the owners of such have a better opportunity of making them more beautiful. From experience I have found it was never satisfactory to class small gardens with large ones.—G. G.

Rose Irish Fireflame.—The accompanying illustration is interesting. It represents two maiden plants of Irish Fireflame whose life-history is briefly as follows: Rather than obtain buds in the usual way, two pot plants of Irish Fireflame were purchased from Messrs. Alexander Dickson and Sons of Newtownards towards the end of July last. The Roses obviously had been grown under glass, and although the wood was well ripened, it was thin, and, consequently, some of the buds were very small, certainly no larger than the ordinary pin's head, so that it was found impracticable, if the bark and bud were not to be injured, to remove the "wood" behind the bud, and the buds were put in with the wood on, just as they were cut from the parent plant. The two stocks shown in the illustration were budded on August 2, and the buds immediately started growing. The photograph was taken on October 13, but before that date several of the crown-buds had flowered and had been removed. On the day the photograph was taken, one plant had thirty-four buds on and the other thirty-three, a good many of which have since flowered. The growth is strong and over four feet in height, and is nearly double as thick at its base as the ordinary Bamboo cane to which it is tied. I think this result out

of doors, obtained in no more than eight weeks from the insertion of the bud, is unusual; it undoubtedly speaks well for the vigour and growth of Irish Fireflame, and at any rate demonstrates its very free-flowering character, both of which points have, I think, been challenged in your columns. The plants are growing in the garden of Mr. E. M. Burnett in this town; they were budded by himself, and have not been fed or forced in any way. The other plant shown in the illustration is a stock budded with Mrs. J. H. Welch, and the growth of the sprung bud is again very vigorous, but is more normal in character. It also was budded at a somewhat earlier date than the stocks bearing the Irish Fireflames.—HERBERT E. MOLYNEUX, *Southampton.*

Nerines Flowering Outdoors.—Your correspondent "C. Q." in your issue of November 15, page 570, sends an interesting picture of Nerine

Chrysanthemums (also, as I am aware, hardy plants!) to devote some of their glass to the Nerine.—F. HERBERT CHAPMAN.

Autumn Planting.—One often sees reference to the importance of early planting, without any regard to the condition of the soil being emphasised by writers when dealing with this subject, that a gentle warning may not be out of place. Early planting is all very well, but just now in most districts the soil is not in good condition on account of the heavy rains, so that those who have work of this kind to do need not be anxious or impatient.—LAURENCE J. COOK.

Longevity of Charlock Seed.—I have quite recently had a plot of grassy ground trenched about twenty inches deep. On the surface of the soil young Charlock seedlings are now growing in great numbers. Of course, they will be destroyed before they attain a large size, but I am prepared to see thousands of seedlings during next year if I am alive. Not a single plant has grown in the grass surface for a long time, but in years gone by the Charlock plants had evidently been plentiful and seeded freely, the seeds remaining dormant in the meantime well below the surface. I have heard that seeds brought to the surface after very many years have germinated, but I have forgotten how long. Perhaps some readers of THE GARDEN may have had some experience in this matter and will state it in these pages.—G. G. [The point raised by our correspondent is an interesting one. We know of a field where, about thirty years ago, some of the old Strap-leaved Turnip was grown for seed. Although none of that variety has been allowed to seed there since and none has been sown, a few used to come up annually until five or six years ago, when we lost sight of the field.—ED.]

The Colour of Oxalis enneaphylla.—Will some of your readers or correspondents kindly shed some light on the colour of *Oxalis enneaphylla*? I have received plants from two sources, and in both cases the flowers are pure white, with a greenish tinge at the base of the petals. I wrote to the nursery where I got one plant, saying it was pure white, and that I understood the normal form had a purple stain at the base of each petal. The firm replied they never heard of *Oxalis enneaphylla* excepting all white.

I turned up THE GARDEN for July 10, 1909, and at page 339, above the name T. Smith, I find a long description of the plant, and the flowers are described thus: "The flowers are white, with a deep purple stain at the base of each petal, and are carried on slender stems. . . . The illustration [a very fine photograph] represents a specimen that flowered this year (1909) in the garden of F. W. Bennett, Esq., Elmhurst, Louth, Lincolnshire. When at its best the clump carried over three dozen flowers." It would be interesting to know if Mr. Bennett's plant is unique.—WEST MEDINA. [The typical species is unmistakably, and to all intents and purposes pure white, though there is no reason to doubt that there are variations of the type. Occasionally, as the flower ages, a slight discoloration may be seen low down, but in no instance have we seen a variety with a deep purple stain at the base of the flower.—ED.]

TWO PLANTS OF ROSE IRISH FIREFLAME EIGHT WEEKS AFTER THE BUDS WERE INSERTED IN THE STOCKS.

Bowdenii flowering in the open, and goes on to hunt that, in common with other correspondents of yours, I am unaware of the hardy qualities of certain of the Nerines. So far as *N. Bowdenii* is concerned, I may say that I have seen flowers of it cut from the open in the South-West of England, and Mr. S. T. Wright of the Wisley Gardens has assured me of its hardiness there; but at present I have no authentic evidence of the hardiness of any of the other species. But all this is rather beside the point. I am very much disposed to think, from what evidence I can gather at present, that the Nerine will never be so charming a plant, and will never exhibit its beauties to such perfection, in this climate when grown outside as when given pot cultivation and the protection afforded by glass; and for this reason I may perhaps be pardoned for reiterating my advice to those who regularly house some

Clematis cœrulea on Warm Walls.—One occasionally sees a plant of this Clematis growing on open walls, but I have never seen one to surpass a specimen growing in a cottage garden in Hampshire and trained on the end wall of the house itself. I suppose the owner has not troubled to train the shoots closely to the wall in a formal manner; indeed, they seem to be supported by cross wires, and the general effect is most pleasing, as the branches, well laden with flowers, depend so gracefully from the wall. Loam, mortar rubble and leaf-soil suit these plants very well, and they form a distinct contrast to other climbing and wall plants in the same garden.—Avon.

Helianthus speciosus.—I see in your issue for October 18, page 528, that an award of merit was given to *Helianthus speciosus* (Tithonia), and you remark that it is probably easily raised from seeds. I have it now in my garden raised from seed sown last spring and obtained from Heinemann of Erfurt. It has not been flowering long, and should probably have been sown earlier. It makes a huge plant 8 feet high, and but for the uncommon and not very beautiful colour of its flowers would, in my opinion, be hardly worth growing. I should think it would be best on poor soil, when it might give more flowers and be less vigorous.—G. STAPLETON, *Rotherwick, Hants.*

Suitable Wood for Pergolas and Pillars.—May I add a word to the able article on this subject in the Special Rose Number of October 11? In addition to the woods mentioned, viz., Oak, Ash and Hazel, we have proven by a number of years' usage that Hornbeam and Larch, when well seasoned and their ground ends tarred, are well fitted to be used in pergola work or as single pillars. The Larch, moreover, can generally be obtained with small branches attaching to the trunk, which fact makes it infinitely more artistic-looking, whether used in a pergola or as a pillar. These projecting branchlets, which, of course, are retained at whatsoever length one wills, are most useful when tying up the growths, because they provide a larger and more irregular surface, thus giving the Roses a less bunched-up appearance.—C. T., *Highgate, N.*

Potting *Dielytra spectabilis* for Forcing.—In THE GARDEN for November 8 there appears on the "Gardening for Beginners" page instructions how to pot certain plants. Such a piece of *Dielytra spectabilis* as is there represented can be easily potted; but if the plants are purchased from dealers—and in nearly every case they are Dutch-grown—the beginner will find himself taced by quite a different problem. It will be found that in nearly all cases each plant possesses but a few long, fang-like roots that are so brittle as to at once snap if any attempt is made to bend them in order to get them into a pot of reasonable size. The novice is then completely at a loss, and puts this *Dielytra* either in too large a pot or does not bury it sufficiently deep, for the long, fleshy roots refuse to be bent. The first time I experienced this difficulty I scarcely knew how to proceed; but, taking the bull by the horns, I cut off as much of the thick, fleshy roots as prevented the clumps from being properly potted. The results were in every way satisfactory, and I have followed it ever since, being fully convinced that there is no need to put *Dielytras* in pots unduly large for fear of cutting away some of the roots.—H. P.

FORTHCOMING EVENTS.

November 24.—National Chrysanthemum Society's Floral Committee Meeting.
November 28.—Show at Hawick (two days).

GARDENING ACROSTICS.

WE have arranged for a series of acrostics during the coming months on the lines of those of last winter, but there will be two important differences, which it is hoped will commend themselves to our readers. First, the acrostics will not be so difficult; and, secondly, the marking will be, as we said in our issue of March 22, on different lines, which will be fairer and more encouraging to all. Instead of each acrostic counting one if the whole and each individual light was right and nothing if any one was wrong, in this second series each light correctly guessed will count one, and also each "first" and each "last." Thus, supposing the whole is China (firsts), Aster (lasts), the full marks will be seven—one for China, one for Aster, and one for each of the five lights C . . . A, H . . . S, I . . . T, N . . . E and A . . . R. Hence, suppose a competitor got everything right but the light I . . . T, he would count six, and it would not matter if he attempted to solve that particular light or not.

Our first acrostic will appear in our issue dated December 6, and we propose to have a series of eight, which will bring them to January 24. Those entering for the acrostics must observe the following conditions:

- (1) Solutions must be addressed to The Editor at 20, Tavistock Street, Covent Garden, W.C., and bear the word "Acrostic" on the left-hand top corner of the envelope.
- (2) If a *nom de plume* is used, competitors must at the same time enclose their own name and address, not, of course, for publication.
- (3) Solutions must reach the Editor within a week of the date of issue in which the acrostic appears. Thus, solutions of Acrostic No. 1 published in THE GARDEN dated December 6 must arrive at the office before or by the first post on December 13.
- (4) A list of those who have sent in solutions, with the number of marks that each one has obtained, will be published in the next issue. Thus, that of those who compete in Acrostic No. 1 will appear in the issue dated December 20.
- (5) We propose to divide the series of eight into two of four each, and to award two prizes at the end of the fourth, and two more at the end of the eighth and last. The first prize in each case will be two guineas, or books of that value, and the second, one guinea. In order to give as many as possible a chance of a prize, the winner or winners of the first prize in the first four will be penalised twelve points, and, similarly, the winner or winners of the second, eight points if they enter for the second four.
- (6) In case of any dispute, the Editor's decision must be accepted as final.
- (7) No solution can be accepted as correct unless it is the one that the framer of the acrostic has sent us as his solution, and which we shall publish in due course. It is impossible for it to be otherwise, as it would lead to much confusion, and it would place upon us [a responsibility which we could not assume.

(8.) In the event of two or more competitors obtaining an equal number of marks for first prize, the first and second prizes will be added together and divided among them.

Solutions, with explanatory notes, will be published as they were last season, only this time we will endeavour to give the list of the competitors for any one acrostic and its correct solution in the same issue.

A GOOD TREE FOR THE PLEASURE GROUNDS.

(*SOPHORA JAPONICA*)

FEW deciduous trees are more attractive in habit and foliage than this Chinese leguminous tree. Though formerly, as the name *Sophora japonica* suggests, considered to be also a native of Japan, it has since been fairly conclusively proved that the Japanese trees, though very numerous, are all cultivated specimens. The year 1763 is given as the probable date of the introduction of the tree to Britain. It is readily recognised by its dark shining green, pinnate leaves, which retain their colour and hang on the trees long after most deciduous kinds have shed their foliage. As a rule, the tree branches at no great height from the ground and forms a large, spreading specimen rather than a tree of great height, though there is a tree at K'w, not far from the Chinese Pagoda, 70 feet high, with a clean trunk for a considerable height from the ground. This *Sophora* is the last of the large trees to flower in the pleasure grounds, being at its best in September. The large branched terminal panicles are composed of numbers of small, Pea-like, creamy white flowers. Flowering so late in the season, the trees seldom mature fruits. A. O.

ROCK AND WATER GARDEN.

THE DESIGNING, CONSTRUCTION AND PLANTING OF ROCK GARDENS.

(Continued from page 572.)

THE first site I will consider is one to which I was called some little time ago, and I may add that the particulars I give here contain essentially the advice given to the client, with a certain elaboration of detail for illustrative purposes. The sketch plan A shows the existing conditions. To those not acquainted with the method of showing existing levels, I must explain that the surface of water in the existing pond is taken as 10 feet above an imaginary datum, and that subtracting ten from any other level given on the plan leaves as a result the height of that particular spot above the surface of the water. This site happens to be illustrative of what I should consider almost ideal conditions for a certain type of rock garden. In the first place, all the straight lines that surround it are in such a position that they can be completely obliterated by judicious plantings; then, it is so situated as to be approached through the more formal portions of the garden, and thence by walks that at every step get further from formality and nearer to Nature, until, at the bottom of the stretch of sloping, or, rather, undulating ground, one arrives at a more abrupt slope still, with a small, natural pond in the hollow at its base. The inclination of the slope is from north to south, with a slight fall across from east to west. The object is to obtain the best possible

SKETCH A, PLAN SHOWING SITE BEFORE TREATMENT.

effect in the least possible area, and to create suitable positions for some alpine, but more marsh plants and aquatics. The water supply is a natural one, coming from a higher level, and in case this should in abnormally dry seasons fail, an artificial supply is laid on. It will be seen from the plan that the banks slope steeply towards the water-level, the pond lying in a sort of valley. Now the first question to ask ourselves is, "Assuming that rock were already in existence here, in what formation would it be found?" The valley itself is to all appearance a "wash-out"; the contour of the banks gives the impression of their being gradually worn away by successive torrents of water passing that way during abnormally wet seasons. Had there been underlying rock here, and a fault in the stratification occurred, what is more natural to suppose than that in the course of time the mass had become disintegrated by the action of the water, and particles washed away, leaving the more or less jagged edges exposed at

some points, while at others the subsidence of the soil from above had created long sloping banks. Here, then, is the formation that Nature, given one more elementary condition, would have produced in this position—long sloping banks, broken with rock outcrop, the lines of which show not only more or less stratification, but also the wearing action of the water has scarified and worn distinct crannies and crevices. Certain portions of the disintegrated masses have fallen at irregular intervals from the main outcrop and lie helter-skelter at

various points along the banks and in the water. Some of these become half buried as the upper soil crumbles down between them, or as weeds germinate, grow, die and decay among them, thus filling the interstices and forming rich beds for future generations of the vegetable world to thrive in.

There is, I know, a school of rockery constructors who adhere rigidly to lines of stratification, and are inclined to ignore the accidents of Nature, with the result that their productions sometimes become a series of more or less pronounced lines that fail to adequately resemble the work of Nature, inasmuch that they look too trim and tidy—too deliberately "arranged." Nature is rather a slutt in her work; she delights to drop untidy masses of all sorts of things about, and then redeems her character by covering them up picturesquely; and it is by taking full cognisance of the careless distribution she makes of her rocks, when she separates them from the main mass, that the really successful rock garden is brought into being.

Here, then, is the ideal she sets before us; now to proceed to develop it. An artist about to paint a picture prepares a few studies in proportion to the work contemplated; an architect prepares plans and designs to scale and tests the effects of

C.—TRANSVERSE SECTION ACROSS PLAN B.

his aspirations on paper; and the successful rock garden is the one that is carefully thought out and planned previous to its commencement, although it is quite impossible to accurately forecast all the details of the effects to be obtained.

In the sketch plan B will be seen my suggestion for dealing with the site. C is a transverse section through the same. By comparing these with the plan A it will be seen that the pond is to be somewhat enlarged. Advantage is to be taken of the difference in levels of some 8 feet or 9 feet between the water supply and the level of the water in the pond, to create two smaller rocky pools at different levels in the hillside, the water finding its way to the pond through water-worn crevices in the stone, forming in effect miniature cascades (see Section A B). The general lines upon which the stone is to be arranged are shown in the plan, also the position and direction of the paths. In fixing the positions for the various masses, their relation to every other mass must be carefully considered, and sufficient provision must be made for planting positions. The results of the ultimate development of this design are seen in two photographs taken after the stone was placed, but before planting. It must, however, be borne in mind that the use of the plan is rather to get a general idea of the scheme fixed in our mind, as the shape of the stone used will, to a very great extent, modify any preconceived notions when it comes to the actual placing of the stone.

THE ROSE GARDEN.

IN A HAMPSHIRE GARDEN.

NOTES ON SOME NEWER ROSES.

HYBRID TEAS FOR EXHIBITION.

(Continued from page 574.)

Mrs. F. W. Vanderbilt (S. McGredy and Son, 1913).—A very beautiful Rose this, the finest product of all the crosses that have been made with Lyon Rose. It is a more vigorous grower than the majority of the Roses that have this blood in their veins, and, fortunately, too, does not seem to have the habit of "dying on ye," as the Irish say, that so far all the pernetiana Roses have got very badly. I am hoping that as they get further away from the original parent, so will this very bad fault be eradicated. I am very much afraid for this reason, if for no other, that Rayon d'Or will never make a satisfactory bed or ever be much good as a cut-back. Mrs. F. W. Vanderbilt is a gold medal Rose, and although not a very big flower, is a very beautiful one, both in colour and shape—pale orange, shaded deep apricot, almost copper colour, very free-flowering, and will make a magnificent splash of colour in a bed of a kind that is not common in our gardens. Asked if it is any good for exhibition, I should say sometimes, if you are lucky, you will get an early flower big enough. The shape is there, but it is on the small side for the exhibition box. Fragrant.

ANOTHER ILLUSTRATION TAKEN AFTER THE ROCKWORK WAS COMPLETED.

I know one would expect plenty of petals, as a matter of fact there are frequently not more than three or four rows. I had a really magnificent flower of great size and apparent substance that stood for days on the plant, and I out of curiosity subsequently counted the petals, to find fifteen only. A normal Rose would have at least sixty, Bessie Brown 120 or more. Its petals, if few in number, are the largest of any Rose that I have come across. It keeps its shape in a truly wonderful fashion, and can be strongly recommended to the exhibitor. This has been the third season I have grown it, and it stood almost as well in the hot season of

SKETCH SECTION ON LINE "AB"

ARRANGEMENT OF POOLS AND SMALL CASCADES AT NORTHERN END OF PLAN B.

Mrs. Forde (Alexander Dickson and Sons, 1913).—This is the only Rose out of the six new varieties that Messrs. A. Dickson and Sons are sending out this year that they call an exhibitor's Rose—the other five are labelled decorative—and a very fine exhibition Rose Mrs. Forde will make. Beautiful spiral shape, of good size and substance. The colour is delicate pink flushed rose, a delightful combination. The petals are almost circular, and have the usual yellow base that one connects with Tea blood. Distinctly fragrant, with a scent all its own, of a fruity kind that the raisers call tangerine; but I cannot say that I should quite call it that. Altogether a beautiful Rose that will be welcome in our gardens. I see I marked it as one of the best of the new seedlings that I saw at Newtownards last year. It is a good strong grower, and I shall look forward to flowering it next year with a good deal of pleasure.

Mrs. J. H. Welch (S. McGredy and Son, 1911).—This is one of the curiosities among Roses. It is a veritable balloon, for though it is, as shown, of the orthodox shape, and if one did not

SKETCH B.—PLAN OF ROCK AND WATER GARDEN FOR SITE SHOWN IN PLAN A.

1911 as it has done these last two years. It occasionally comes a particularly brilliant colour, as striking as anything I know in pinks, but its normal colour is quite good. It is a tall and whippy, but not particularly vigorous grower. The buds have a very large calyx; unusually so. It has been well shown by the trade and amateurs alike throughout the season, and has come to stay, notwithstanding its peculiarities. It is slightly fragrant, and even when fully open with flowers as large as saucers it is beautiful. It figured in Mr. Mawley's selected twenty, and I see occupies quite a high place, as I should have expected, in his Analysis of exhibition Roses. It is a gold medal Rose.

Mrs. Muir MacKean (S. McGredy and Son, 1912).—This Rose can be best described as an improved Mrs. A. E. Coxhead. The colour is deeper and more of a crimson carmine. It is also a good shape, the petals perhaps not quite so large as Mrs. A. E. Coxhead, but very free-

in the nurseries. I think it will quickly take a prominent place, as the flowers seemed so uniformly good.

Mrs. Wallace H. Rowe (S. McGredy and Son, 1912).—A Hybrid Perpetual like growth, but a very fine flower severely handicapped by its colour description. In all catalogues it is called Sweet Pea mauve—enough to prevent anyone buying it. It is really a good carmine pink, quite a pleasant shade. It is robust rather than vigorous. The flowers are of good substance and finish, and invariably come a good shape; the colour lasts and does not fade.

St. Helena (B. R. Cant and Sons, 1912).—This Rose has been frequently exhibited during the season, but I cannot say much about it from my own experience, as something went wrong with my plants. It is a beautiful shape, with a good spiral centre reminiscent of Joseph Hill, both in colour and form. Of the twenty new Roses

COLOURED PLATE.

PLATE 1481.

THREE GOOD GARDEN ROSES.

WE are frequently asked to name Roses that can be relied upon to give a good display over a long period, and which are, in other respects, well adapted for massing and thus creating good effects in the garden. Fortunately, there is now a good host to select from, and the three shown in the coloured plate presented with this issue ought to be grown wherever good Roses are appreciated. All are of comparatively recent introduction, and all can be obtained from any good Rose nurseryman at nominal prices. If we had to select the best of the three, our choice would be

Arthur R. Goodwin. This is purely a garden Rose, and of no use for exhibition except in those classes specially provided for Roses of this kind. It makes a very compact and neat bush, never mildews, flowers from June until well into October, and the blooms present several different phases of colouring. The half-opened buds are very charming indeed, the colour at that stage being a sort of vivid coppery orange, with a suspicion of scarlet on the outside. Two other stages of development and colouring are well portrayed in the coloured plate. Unlike most other Roses, the petals hang on a long time after the flowers are full blown, a feature that is desirable in a garden Rose, as the display is thereby prolonged. Arthur R. Goodwin was put into commerce in 1910 by M. Pernet-Ducher, and is classed as an Austrian Hybrid. The next in order of merit is

Lady Alice Stanley. This Hybrid Tea really ought to be bracketed with Arthur R. Goodwin if it behaves as well with everyone as it has done with us. It resembles Mrs. Wakefield Christie-Miller in colour, but the flowers are of much better shape, and some that we have had this year have been quite up to exhibition standard. The bush is vigorous, very neat, and the large leaves of leathery texture, so that they withstand mildew effectively. The blooms are borne on stout, erect stems, and the depth of colouring to be seen

in them as they unfold is marvellous. On the 8th inst. we cut two beautiful flowers of this from one bush, and we owe a great debt of gratitude to Messrs. McGredy and Sons for sending it out in 1909.

George C. Waud we approach with some diffidence. It is decidedly below the two others as a garden Rose, yet it must be grown for its colouring, which is quite unlike that of any other variety. The official description of it is rose suffused orange and scarlet, but that scarcely conveys to the mind the vivid, fire-like intensity that one sees in the garden. But, alas! it is not mildew-proof, although not nearly so badly addicted to it as some varieties. Then, the flowers often come with rather badly-shaped centres. But it is vigorous, free and sweetly scented. It was sent out in 1908 by Messrs. Alex. Dickson and Sons, and is classed as a Hybrid Tea. We are indebted to Messrs. H. Merryweather and Sons of Southwell, Notts, for the flowers from which the coloured plate was prepared.

AN EFFECTIVE GROUPING OF PERENNIAL CANDYTUFT, THRIFT AND SAXIFRAGES IN A LONDON GARDEN.

flowering and deliciously fragrant. A good grower and not subject to mildew, very reliable and always in flower.

Mrs. Sam Ross (Hugh Dickson, Limited, 1912).—A beautiful Rose this, useful for both purposes, a light yellow, shading to a deeper colour, with a flush of buff on the outside of the petals. It has not yet had time to get known, but it will be wanted when it is. A refined Rose, very free-flowering, a good grower and sweetly fragrant. I think it is the best of this firm's 1912 set. Gold medal at the Royal Botanic Show, 1911.

Mrs. R. D. McClure (Hugh Dickson, 1913).—This is a beautiful-shaped variety of a clear salmon pink self; good pointed flowers. A fine, strong, vigorous grower, free-flowering, that holds its flowers well erect. I was very much taken with it at the Belfast Show last year, where it received the gold medal, and my impressions were subsequently more than confirmed when I saw it growing

it found its way into the first half-dozen as a result of the combined voting of the trade and amateurs, so there is not much fault to find with it. The raisers have been able to show it consistently throughout the season. It was awarded the gold medal of the National Rose Society at the Southampton 1912 Show.

This concludes my notes on the Hybrid Teas that might be useful to exhibitors. Next week I will deal with the Teas for exhibition, and then start on the decorative or garden Roses, which are a popular class.

Southampton. HERBERT E. MOLYNEUX.
(To be continued.)

[We take this opportunity of thanking the many readers who have sent us letters of appreciation respecting Mr. Molyneux's notes. Some of these have come from Hong-Kong, New Zealand, and other distant countries, where Rose cultivation is evidently making great progress.—Ed.]

THREE GOOD GARDEN ROSES—

Yellow: Arthur R. Goodwin.

Pink: Lady Alice Stanley

Red: George C. Waud.

THE FLOWER GARDEN.

DAFFODIL NOTES.

New Zealand Jottings.—I was interested to read the cutting of the Auckland 1913 Show, sent by Mr. Chapman, in *THE GARDEN* of November 1. I can supplement that by an extract from the *Lyttelton Times* of the Canterbury Show, where, too, a large number of seedlings were shown: "Special interest at this show centres in the seedling exhibits, and these were on this occasion represented by a very fine array of blooms. Four of these, shown by the Hon. R. H. Rhodes (Tai Tapu), were awarded the society's certificate. They comprised Sea Swallow, a sport from Seagull; Otahuna, a large cream-coloured trumpet with a white perianth; Mararoa, a white-perianthed incomparabilis; and Minaret, a pale canary-coloured trumpet with a white perianth. All these blooms were of large size and great beauty, and some were considered superior to the best English seedlings of the kind of which there is record. . . . Mr. Biggs showed a quaint novelty in the form of an extremely attenuated and slender yellow bloom, a seedling from cyclamens and a trumpet."

It is pleasant to know that our New Zealand brethren are just as busy as we are with seedling-raising, and that their money has not been spent in vain, for many are the golden sovereigns that they have sent to the Old Country for "good things," and it would be discouraging to a degree if there were no results to reward their courage and their pains. I do not, however, think it is *Sic transit* "everything here" just yet.

Sporting in Daffodils.—Up to now authentic cases of permanent sporting have been very few. Barbara Holmes is said to have come from Barri conspicuus. This and a sport of my own from Seagull are the only ones I can recall at the moment. The appearance of Sea Swallow is most interesting. It at once suggests the thoughts: "Has the time of life come when Seagull will give sports?" and "Will other varieties have this tendency?" I imagine that such things are possible. For a good many years I held the entire stock of China Ware, which I bought from the late Mr. Haydon. Every spring I have invariably found several flowers in which there was a considerable amount of a deeper yellow than the normal pale citriny shade. Latterly I have used such flowers in "crossing," in the hope that their unstable tendency may produce something novel in their offspring. I have never noticed any other variety so sportive. Are there others, and are any of them permanent?

New Zealand Shows.—From a private letter I am able to compile an approximate list. It

may surprise some readers to know that there are at least four centres in the two islands where special shows are held this season—Auckland, end of August; Christchurch, September 12 and 13, and a second on September 24 and 25; North Otago, September 25; and Dunedin, October 1 and 2. There may be more; if so, I hope some New Zealander will kindly supply the omission.

Narcissus Beethoven.—Some readers may remember that I once sang the praises of a Van der Schoot variety called Astra. I feel I owe everyone

this particular time to do so because I see, in *THE GARDEN* for November 1, a good illustration of it in Bees' advertisement, and, as they say so truly, "lest you [that is, I] forget." It is a most attractive garden plant, and it is "not so dusty" in pots under glass. It has these qualities to recommend it: (1) Colour—a sunshiny yellow, almost exactly the shade of the lovely Autocrat; (2) earliness—a real good doer to come in early is wanted; (3) floriferousness—it is "very free"; (4) constitution—most robust; (5) rapid increaser; (6) good in pots; (7) distinct shape—the curious, roughly jagged trumpet is striking. Points against it: None that I know of, except it be length of stem, which might be a bit longer from a cut flower point of view; or its shape, which I think pleasing and graceful when I am an ordinary mortal and not one of the modern "curious"—a judge at a show. I recently took part in the letter-writing in a very lengthy discussion *re* the judgment of the *chefs* at the Royal Horticultural Society's Vegetable Show. I said a vegetable for show is one thing and a vegetable for use is another. (If a good cook does not know what he wants for cooking, why should a gardener?) So with Daffodils. "Show" and "garden" varieties may be the same, but more often, perhaps, they are not. It is the garden award that I pin on Beethoven's breast. Having just said all this, may I here be allowed to say I read the two articles by "Somerset" with great interest? My reply is summing.

JOSEPH JACOB.

P.S.—Since writing the foregoing I have been told by a grower of cut flowers for market, who had some of my Beethoven in his garden last spring, that he found it to be a great favourite and that it commanded a ready sale.—J. J.

A NOVEMBER FLOWER (KNIPHOFIA MULTIFLORA). THIS HANDSOME SPECIES IS WORTHY OF A SHIELDERED NOOK IN SOUTHERN GARDENS.

an apology for doing so. It is a lovely, uncommon shade of pale yellow, and for several years did splendidly. But in the very next season after my remarks appeared "something happened," and now I would be glad to take sixpence a hundred for all I have. Once bitten, twice shy. I have waited patiently before I "passed my opinion" on another of Messrs. Van der Schoot's bantlings—Beethoven. I am making no mistake in writing this down as a first-class variety, and I have chosen

some forgotten shape and a pink flower at the top of the stem, don't you know, &c., is often revealed to me by a process that I claim no credit for, as it must be more intuitive than deductive. But a few questions like those one uses in playing the good old game of "clumps": "Are its leaves simple like a Violet's?" "No." "Then perhaps finely cut like Fennel?" "Yes." "Is it a Cosmos?" "Ah, yes, I remember now that's what Mrs. Brown called it." And there we are;

TWO WHITE KNIPHOFIAS.

I HAVE for many years rather prided myself on the possession of a sort of second sight that comes to my aid when I am asked to name a plant from an imperfect description. Of course, when I am questioned as to a puzzling tree, I ask, "Can it be a Hornbeam?" and in ninety-nine cases out of a hundred it is; but I mean more than that, and the puzzling plant that has roots—well, just ordinary roots—in the ground, you know, and a stem growing straight up and green leaves of

but I felt at the beginning it was a *Cosmos*, and goodness alone knows how or why. There are two *Kniphofias*, though, that, unless I had just seen one of them, would, I feel almost certain, never come into my head even if fairly well described. One's idea of a *Kniphofia* is that it should be a Red Hot Poker, and a white heat is not expected of it. Yet there are two, not often-seen species, in which the flowers are unusually small and white or slightly greenish, and are produced on spikes unusually long and slender in build for this genus. *K. modesta* was discovered by Mr. Tyson in Griqualand East in 1884, 6,000 feet above sea-level, and later by Mr. Medley Wood in Natal, whence plants were sent to Kew. It is a charming and dainty plant, but, unfortunately, none too robust, and in spite of my care I could not make it happy here in the open air, and it died after a short illness.

The other, *K. multiflora*, is a much more robust plant, also from Natal, and makes a fine specimen plant in favoured climates, such as those of Cornwall and Southern Ireland. Its long, channelled leaves are of a pleasingly rich green, and have an air of distinction that produces a sub-tropical effect. The flower-spikes are narrow, but densely furnished for a great length with the small, tubular, greenish white flowers, and have something of the general appearance of some species of *Eremurus*. Unfortunately, they seldom attempt to open before late October or even November, and so in all but the warmest gardens of our islands they are in most seasons so severely snubbed by Jack Frost that they fail to get over his cruelty. This season has been wonderfully favourable to such late-flowering plants, and a bed of this *Kniphofia* in front of the Orchid Houses at Kew has flowered splendidly, producing over sixty spikes. Some good specimens were exhibited at the last meeting of the Royal Horticultural Society also. It is a plant quite worthy of a sheltered nook and a little protection, such as a mat will afford, on nights when frost threatens in mid-October; and then in some seasons it will make a fine display just when most of the outdoor plants have ceased flowering, and is perhaps all the more welcome on this account.

Waltham Cross.

E. A. BOWLES.

SWEET PEAS: SOME REFLECTIONS AND HINTS.

THE season now closing has not been kind to the Sweet Pea. From the time of planting right through its growing period it has had to withstand the most inclement weather. A period of cold, damp days immediately followed planting out, and little or no growth was possible; then in May came a sudden spell of almost semi-tropical sun-heat, with drying winds and cold nights, and later on, when the sun would have been beneficial, it kept itself hidden in a sky of hodden grey. Could anything be happy under such conditions? Yet if a brief on behalf of the culture of the Sweet Pea were needed, the very inclemency of the weather would support it, for at all the prominent shows some wonderful exhibits of Sweet Peas were staged, showing that, despite the prevailing un congenial conditions, the Sweet Pea had flourished, amply repaying the grower for the labour bestowed on it with its wealth of fragrant flowers. A survey of the season reveals an increasing interest by the public in this lovely flower. At the principal London and provincial shows the biggest crowds were generally round the Sweet Pea exhibits, and although no startlingly striking

novelty has attracted attention, yet among this year's novelties are several of sterling worth which will replace some of the older varieties, as they supersede them both in size and colour. A pleasing and gratifying fact frequently noticed was that Comtess Spencer, Constance Oliver, Dorothy Eckford, Etta Dyke, John Ingman, Mrs. Hugh Dickson, Tom Bolton and several other old friends still hold a prominent position among the exhibits, showing that they retain the admiration they immediately gained on their introduction several years ago, and are fulfilling all that was predicted of them.

KNIPHOFIA MODESTA, A DAINY SPECIES WITH SMALL WHITE FLOWERS.

The most disquieting fact recorded this summer, and one which is more fatal to the progress of Sweet Pea culture than either streak, mildew, or any other disease, is the awful "mixture" which resulted from growing seed sent out by some seedsmen. Deplorable examples of inpure seed were seen again and again, and this flooding of the market with unwholesome seed is more venomous than any tung attack and more invidious. "Spotting" will always occur more or less, and some varieties are very prone to it; but the majority of our leading firms have the welfare of the Sweet Pea at heart, and pay the most scrupulous care in "rogueing" that their stocks can be thoroughly relied upon,

and it is false economy to buy seed from other than the best raisers. Of course, one has heard the inevitable complaints of disease (streak, leaf spot and mildew), and some sorry wrecks have been seen. However, the conclusion arrived at is that the cause of the majority of failures is ignorance—culpable ignorance, one might say, in many instances. One grower complained of all the buds dropping, and why? A glance upon the surface of the soil revealed sufficient chemical for a row fifty times the length, and an extraordinary amount of manure also had been trenched into the ground previously to planting. Numerous complaints of leaves turning yellow and plants refusing to grow have resulted, in most cases, upon examination to be the result of "digging a grave" for the Sweet Peas. A veritable reservoir of putrid mud and manure was what the Sweet Peas were expected to delight in. The word "trenching" has many deaths laid at its door. Several not failing in cultural detail were sadly disappointed, and one in particular had given his Sweet Peas almost perfect culture, and yet not a bloom was the colour he saw at the National Sweet Pea Society's show. How could that be? I give his list of excellent varieties: Thomas Stevenson, Afterglow, Lady Miller, Charles Foster, Flora Norton Spencer and Barbara. "Protection from the elements" was suggested, and although much surprised, he followed the advice and in a few days beheld blossoms equal to those which had captivated him at the show. Thus it is that through ignorance of cultural details, or of the habit and nature of the variety selected, many have met with disappointment and have been deprived of the joy and beauty which is peculiar to the Sweet Pea alone.

Much has been written about the Sweet Pea, but many people do not yet know its ease of cultivation and are often oblivious to its history. The purpose of this and future articles is to place a simple, concise statement of fact before the reader, dealing with every phase of Sweet Pea life, and, if possible, to remove the ignorance which is the cause of most of the failures so often attributed to either the seedsman or the Sweet Pea. A word of warning must be added against a too literal adhesion to the hints set forth in any one paper. It is impossible to generalise for the whole country; but the suggestions made will be such that, with the combination of common sense and knowledge of the particular district concerned, will prove to give the desired successful Sweet Peas. The first consideration, as it is autumn, is the stock. As has already been mentioned, certain growers have either wittingly or unwittingly sent out unixed and untrue stocks, and such seed has been, and is, a source of much vexation. Every grower of Sweet Peas should therefore procure his seed from a reputable firm, and preferably from one recognised as a raiser of first-class varieties. The advertisement columns of *THE GARDEN* will provide the names of several leading firms who grow their seed under their own supervision, scrupulously roguing it, thereby guaranteeing it true to name and of excellent quality. Having obtained a catalogue, buy the seed as early as possible in the autumn, and so be assured of getting the varieties you require.

Selection of Varieties.—The selection of suitable varieties is by no means the task of a novice, but requires well-considered discernment between the many names that meet the eye in every list. As the subject is so important, it will receive full treatment in a future article, together with criticisms of some of the novelties offered this autumn and a list of the best. S. M. C.

GARDENING FOR BEGINNERS.

HOW TO PLANT ROSES.

THE increasing love of Roses every year leads amateur cultivators and others to plant the trees in great numbers each autumn, and, indeed, as late as March in the following spring. Unless unavoidable, late planting should not be the rule. It may, and does, result in retarding the new growths in the spring, and thus they escape injury by late frosts; but the plants sometimes suffer afterwards when long spells of dry weather come. Autumn planting is best. Before any Rose trees are put in, the different positions for them should be selected, so as to plant those varieties in each section that will answer the purpose best, as Roses are valuable plants for pergolas, arches, arbours, pillars, walls and trellises, as well as for lawn and other beds.

The Soil.—This, the rooting medium, is a very important item in connection with Rose-growing. It varies considerably in different parts of the country, and where poor or gravelly must be improved. A good friable loam of a retentive nature is the best, and, where such obtains, very little need be done to it beyond breaking it up to a depth of at least 18 inches. The top portion must be kept there, the bottom being broken up, but retained below. Poor soils must be treated in the same way, and, when possible, some soil of a heavier nature added. The actual manuring of the ground should not be done before growth is free early in May.

Grassy Ground.—In new gardens and where fresh land is dealt with, it often means that the cultivator must deal with grassy ground. Now, such land needs special attention, and if well treated the Roses will do remarkably well in it. There

HOW TO PLANT ROSES IN THE OPEN GARDEN.

is no opportunity to trench the ground, but it may be treated in an almost like manner, the Roses being planted at the same time. The ground must be deeply dug and the subsoil well broken. The positions for the Roses should be marked as the work proceeds, taking care to chop up and

bury the grass portion a little deeper than between the positions marked for the plants.

How to Plant the Roses.—When received from the nursery, if the weather is open, unpack the bundles at once and soak the roots in water, and then get the Roses planted as soon as possible. In Fig. A, No. 1 shows a medium strong Tea Rose, and No. 2 a strong Hybrid Perpetual. All badly-damaged roots, as shown at No. 3, must be cut off. Make holes—before the trees are received—as shown at No. 4, having them large enough to accommodate the roots without undue cramping. The crosses in No. 5 show how to dispose the Roses. An edging of London Pride or *Cerastium tomentosum* is very effective. No. 6 shows how to plant a Rose so that its roots will be clear of the post, No. 7. Roses near garden paths may be planted and trained on wires as shown at No. 8. Painted iron rods should support the wires, every third bar being a little stronger than the others.

How to Plant Roses Under Glass.—The principle of planting Roses in brick pits under the stages, as shown at No. 1, Fig. B, is much better than planting them in the sour soil beneath, as shown at No. 2. The plants in pits are stronger. When planting against outside walls, the Roses should be so put in that their roots are quite clear of the foundation portion of the wall, as denoted in No. 3. Plant standards in just the same way as dwarfs, but keep the stake clear of the stem, as shown at No. 4, and have the stake long enough to allow of the head being secured to it, as shown at No. 5. Roses planted for pegging-down purposes must be in well-prepared ground, as it will prove difficult to attend to their roots afterwards. Peg down the shoots as shown at No. 6, placing the branches as evenly apart as possible. No. 7 shows how the surface mulch must be laid on to protect the roots and not unduly bury the stem. G. G.

METHODS OF PLANTING ROSES UNDER GLASS, AND FOR PEGGING DOWN OUTDOORS.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Pleasure Grounds.

Lawns.—To keep these in really good condition they should be periodically weeded, and at no season do the weeds come out easier than at present. Though there are several weed eradicators to be had, I have not yet found one to beat the old two-pronged Daisy grubber.

The Rose Garden.

Where the Rose garden is in close proximity to large trees, considerable difficulty will be found in keeping the roots of the latter from robbing the Roses, and it is astonishing how quickly the good soil of the Rose-beds gets monopolised by the tree roots unless precautions are observed. In some instances I have seen galvanised iron put round the beds on the side from which the roots come; but, in addition to being expensive, the roots soon find their way either under or over this. The best plan, I think, is to take out a narrow trench around the tree or trees at a distance that is not likely to permanently injure them, cutting all the roots and filling in again; and if this happens to be a few feet from the Rose-beds, it should prove effective for at least two or three years.

Rose Planting must be pushed forward as much as possible. The late growth of the Roses has prevented them being lifted very early; but if the long growths are shortened back when the plants are lifted, and not allowed to remain out of the ground too long, the plants should be in a better condition to stand the winter than those not shifted. I have frequently noticed that replanted Roses have suffered much less from frost than others not so treated.

Plants Under Glass.

Sweet Peas for flowering under glass should be making a nice sturdy growth, and though it is not imperative that they should be removed from the cold frame, a stage or shelf in a quite cool house will suit their requirements well. If the plants are in quite small pots, give a shift on as soon as the roots appear to require it; if in single pots, $4\frac{1}{2}$ -inch will be large enough; if several plants in a $4\frac{1}{2}$ -inch pot, then a 6-inch or $8\frac{1}{2}$ -inch should serve them till they are placed in their flowering pots early in the year.

Poinsettias that may have been used for the conservatory or been used for the decoration of the house should be placed in a cool house and gradually dried off. Late batches must be carefully treated to keep the bracts in good condition, careful watering and a moderately dry atmosphere being quite essential now they have attained full size.

Euphorbia jacquiniæflora should still be growing, and a little weak liquid manure may be employed to help them to push their flower-buds. As this flower lasts well, it is advisable to keep it in reserve, as good, bright subjects are not so plentiful after Christmas as they are at present.

Zonal Pelargoniums.—These are now making a brave show, or should be, and to preserve the flowers in good condition a dry atmosphere must be maintained, with plenty of air during the day. Fog is perhaps the worst enemy of Zonal Pelargoniums during the winter, so during foggy weather the ventilators must be kept practically closed, or the whole of the opened petals will drop. Young plants rooted in the autumn and intended for an early summer display must be kept growing steadily in a moderately warm house or frame near the glass, stopping the young plants when a few inches high to induce a bushy habit of growth.

The Vegetable Garden.

Broad Beans sown early in the month will owing to the unusually mild weather, be quickly through the ground, and it may be advisable to pull a little soil over the young plants if sharp frosts are expected. If the soil is in a good, workable condition, it might be wise to make another sowing, as the frost is much more likely to injure large than small plants during the months of January and February.

Peas should be sowed as they come through the soil, to prevent the ravages of slugs. Also it

is advisable to place black cotton over the rows or cover them with Pea protectors to keep off the birds.

Celery.—In the event of severe frost, a covering of dry straw should be given to the rows to protect the hearts, removing it as soon as the spell of frost is over. On heavy land it is sometimes advisable to place ridge-shaped boards over the rows to keep the water off; but it is only necessary where the soil is of such a nature as to rot the hearts during wet weather.

Fruits Under Glass.

Early Vineries.—In most establishments where there are two or more vineries, the end of November or early December is a very suitable time for starting the early house. The first few days after closing the house the temperature should not be raised too high, even by sun-heat, and no artificial heat should be required. If the weather is fine, a light spraying over the floor, walls and rods during the early part of the day should ensure sufficient moisture in the atmosphere of the house, which may be slightly increased where fire-heat is employed.

Early Peach-House.—The same remarks apply here, and an even more strictly moderate temperature must be employed at the commencement. Early Peach trees have a tendency to drop their buds; hence the necessity of a very gradual rise of the sap. If very light syringings are employed and the roots are in a nice moderately moist condition, the chances are they will come away well; but no attempt at hurrying the trees must be made till the fruits are set.

Pot Vines and Peaches should also be started, observing the same cultural conditions, but it will be noted that these will come away quicker than the trees and Vines established in the borders, as the pots will get warmed through very quickly. Watering must be carefully done, and though the plants do not require much water at this season, they must on no account be allowed to get dry.

THOMAS STEVENSON,

(Head-gardener to E. Mocatta, Esq.)

Woburn Place Gardens, Addlestone, Surrey.

FOR NORTHERN GARDENS.

The Flower Garden.

Trenching.—The past summer has supplied an object-lesson as to the advantages of deep cultivation. It is to be commended for almost every class of plants; but for such subjects as Sweet Peas, Dahlias, Hollyhocks and other gross feeders it is imperative if good results are to be obtained. Bastard-trenching, or double digging as it is sometimes called, is preferable to trenching proper. By the former method the top and bottom spits are left in their respective positions; whereas by the latter method the cold, inert soil is brought to the surface.

Protecting Christmas Roses.—These will be improved in quality by having the protection of a frame with abundance of air. Should severe frost occur, however, the lights should be closed, and a mat be thrown over each light, or the blooms will suffer to some extent.

Cleaning Gladioli.—If the stock was placed in boxes among sand or light soil and stored in a shed, the foliage will have ripened by now. The plants should be gone over on a wet day, the foliage removed, and the corms cleaned and stored away in a cool, dry place until wanted in spring.

The Rose Garden.

Supports for Climbers.—Attention should be given to the condition of the various kinds of supports to which climbers are trained—trellises, poles, arches, pergolas, &c.—and where any repairs are necessary, they should be carried through during the dormant season. The painting of any of those subjects requiring it should also have attention if the weather is favourable.

The Shrubbery.

Pruning Deciduous Shrubs.—With a few exceptions this work should be proceeded with when frost is absent. Exceptions are Forsythias and varieties of *Pyrus japonica*, which should both

be pruned immediately after the plants have flowered. The Forsythias are generally grown as climbers, but they make excellent bush plants for the shrubbery.

Plants Under Glass.

Autumn - Sown Annuals.—Schizanthuses, Mignonette and varieties of *Clarkia elegans* require close attention during the winter months. Pinching must be resorted to, Schizanthuses requiring the operation to be performed several times to induce a bushy habit. Mignonette and *Clarkia* require careful watering. The latter should be kept rather dry, or damping is sure to ensue.

Pruning Climbers.—Attention should be given to this work. Ivy-leaved Pelargoniums and Fuchsias should be cut well back to the old wood, and a good general rule is never to retain more shoots than can have their foliage fully exposed to the light.

Vitis henryana.—This beautifully-variegated Vine deserves to be more widely known. I have seen it recommended for the open wall, but for Scotland generally I fear it must be regarded as a conservatory climber.

Fruits Under Glass.

Pot Fruits.—If not already attended to, any trees requiring re-potting should have attention forthwith. The aim of the cultivator, however, should be to retain the plants in their present pots as long as possible, consistent with their being maintained in a healthy and fruitful state. These conditions can often be maintained for a number of years by judicious top-dressing and feeding. After attention has been given to re-potting and top-dressing, the pots should be plunged in some loose material, such as spent Hops or Coconut fibre, to protect the roots from frost.

The Hardy Fruit Garden.

Pruning Wall Fruit Trees.—This work should be pushed forward when the weather is dry and frost does not occur. The work of pruning Pears is much the same as that of pruning Apples, referred to last week. The Apricot bears its fruit partly on wood of the previous year's growth and partly on spurs two or three years old. All older spurs should be periodically cut away. Young shoots should be laid in about ten inches or twelve inches apart and be shortened to about a foot in length. The Peach bears on the previous year's wood, and young wood should in summer be laid in as advised for the Apricot. The shoots which have borne fruit during the past season should now be cut away.

Protecting Figs.—Where Figs are grown on the open wall, they should be protected during frosty weather by a screen of Broom, Heather, Bracken or Wheat straw.

The Vegetable Garden.

The Rubbish-Heap.—If the full value of the rubbish-heap is to be obtained, it should not be allowed to lie until by natural processes it again becomes a mass of earth, but should at the end of the season be turned over and a considerable quantity of quicklime incorporated with it. The lime will accelerate the process of decomposition and render the mass available for the vegetable crops to assimilate its fertilising properties at the earliest possible moment after it has been dug into the soil previous to cropping in the spring.

Herbs.—All herbs which have not already been cut down should now be cut over. The ground should be cleared of any remaining weeds and then be dug over.

Horse-Radish.—This is often a much-neglected crop. On account of its tenacity of life it is a popular fallacy that it may be allowed to take care of itself. On the contrary, if thick, succulent thongs (the only kind worth having) are to be produced, the crop must be very liberally cultivated. Now is the time to prepare for spring planting. Dig a trench from 2½ feet to 3 feet deep and fill it with decayed vegetable matter, leaf-mould and stable manure; then it will be ready for the reception of the crop in the early spring.

Cauliflower Plants.—Young plants in frames or plant protectors must not be allowed to suffer for the want of water, and, while they must be protected from severe frost, they should be fully exposed in mild weather. CHARLES COMFORT.
Broomfield Gardens, Davidson's Mains, Midlothian.

WISLEY'S NEED OF A COLLECTOR.

THE following letter, which appeared in last week's issue of *Country Life*, is of more than ordinary interest to Fellows of the Royal Horticultural Society and to flower-lovers generally; "Among your many readers there are doubtless a large proportion of those persons whose names may be found in that distinguished list of 13,000 who are Fellows of the Royal Horticultural Society, and I therefore venture to hope that you will kindly ask for the views of those among them who are presumably not only interested in gardening, but are also loyal friends of that fine and important society, on the following criticisms, which are made in the spirit of the lover who cannot bear imperfections in the beloved. There has never been a time, I imagine, like the present when so many new and exciting plants and shrubs have been sent to this country from all parts of the world, when there is hardly a nurseryman of repute who does not send someone to the mountain fastnesses of Spain, Italy or China armed with enthusiasm and a trowel. Mr. Wilson and Mr. Forrest, both sent out by the enterprise of two of our biggest nursery-gardeners, are doing splendid work of this kind, and a special tribute to the admirable and scientific methods of Mr. Forrest was paid by Professor Bayley Balfour at the Primus Conference of the Royal Horticultural Society in April of this year. And yet—the rock garden at Wisley is dependent on the generosity of those Fellows who may choose to furnish it with their gifts of charity and superfluity. Surely the time has come when the Royal Horticultural Society should have a collector of their own. Ought it to be a fact that we owe practically every new introduction of recent years, not to the Royal Horticultural Society, but to private individuals, or the enterprise of nursery-gardeners? I am not expert enough in figures to make any deduction from the balance-sheet of the Royal Horticultural Society, published in the August Journal, but if the Society cannot afford a collector, surely among that 13,000 there are, at least, 1,000 who would gladly give a guinea a year towards this object for the honour of the Royal Horticultural Society and in the interests of horticulture. I am told that the objection to this would be that such subscribers would demand their annual pound of flesh in return in the shape of new plants; but, personally, I do not believe this would be so. I feel sure that they would willingly wait until such time as the plants had been proved and propagated at Wisley, when, possibly, a priority, according to the amount subscribed, might be arranged at the time when we all of us receive that exciting and unexpected little box of plantlets from Wisley. Again, it may be urged that there is a danger in all the indiscriminate collecting that is now going on of certain rare species being exterminated by the zeal and ignorance of the amateur rock gardener, but this is really no argument, as anyone who has visited even the smallest corner of the European Alps knows that 'rarity' means 'locality,' and that in their own habitat these things grow in such countless millions that all the nurserymen in England could not exterminate them. By all means let the Swiss protect their Edelweiss, if they think it worth doing. We do not want it; and, if we do, there are lawns where it grows

in the short alpine turf like English Daisies—just as there are other places where you may sit and munch your unappetising hotel sandwiches on an acre-wide carpet of *Eritrichium nanum*. Again, it may be said that this work should be done by Kew, but the gardens at Kew are not only more limited in space, but are hampered by their proximity to London smoke and fog. Wisley gives up a large amount of ground and labour to the trials of such things as Violas and Dahlias, not to mention such utilitarians as Green Peas and Potatoes, which is work, I would humbly suggest, that might be equally well done by any nurseryman; but if lack of space is any argument against an extensive trial of new trees, plants, shrubs, or alpine plants, surely much useful work might be undertaken by wealthy Fellows with large gardens and expensive troops of highly-trained gardeners, and it would also be done more usefully in different parts of England, under more varied climatic conditions—and it would not be a difficult matter, one would think, to arrange for an annual report from these Fellows, or an inspector from the Wisley Gardens. There is one more point I would like to urge. Referring to paragraph 14 of 'Notes to Fellows' in the last number of the Journal, I find the following: "In a Royal Horticultural Society garden every single detail should teach something," etc. This is an admirable maxim, but I should like to mention (in a low voice) that many of the labels in the rock garden at Wisley teach things which were better untaught. Now, I do seriously think, Mr. Editor, that the gardens of the Royal Horticultural Society ought to be above reproach in this matter. It is not an easy thing to name Saxifrages, for instance, but there are people who can do it, and I maintain that it is a comparatively easy thing to avoid such mistakes as labelling a very common and well-known *Linaria* as 'requiritroba'—which is neither Latin nor anything else—to mention only one instance. No doubt many of these misfortunes arise from Fellows sending plants with illegibly written labels (I would not like to say with falsely written ones), and one does not expect the best rock foreman in the world to know everything; but there are plenty of experts, and why should not someone be asked to see that, at any rate, the labelling is correct? I do not ask for such subtleties as learned distinctions between *Edraianthus* and *Wahlenbergia*, or between *Androsace*, *Aretia*, or *Douglasia*, for the powers that be are not long together of one mind with regard to these high matters; but might we not have, at least, the last name but one? I trust that these remarks may be taken as written in no unfriendly spirit, for, on the contrary, they are written by one who has the honour of the Royal Horticultural Society very closely at heart and owes it much. No. 3786."

An Official Catalogue of Roses.—The official descriptive list of Roses, 1914 edition, just published by the National Rose Society ought to be in the hands of everyone who loves the Queen of Flowers. What "Whitaker" is to the business man, this catalogue is to the Rose-grower, for within its pages he can find a full and accurate description of every Rose worth growing, together with any little peculiarities that it may possess. Then the lists of Roses for various purposes, such as exhibition, bedding, pergolas and pillars, are invaluable, and quite worth the half-a-crown charged to non-members of the society for the handbook. Copies can be obtained from the hon. secretary, Mr. E. Mawley, Rosebank, Berkhamsted

NURSERY NOTES.

MESSRS. WILLIAM CUTBUSH AND SON.

THIS old-established and well-known firm have for many years been regarded by gardeners as one of the best in the country, and it used to be, and still is, said that everything necessary for the garden can be obtained from them. For many years associated with the northern heights of London, to wit Highgate, not far away from Hampstead Heath, they have conducted a nursery business that is second to none in the country, and at the time of our visit in early October it was evident that it was not their intention to be left behind in the race for up-to-date methods that is now taking place on every hand. For that reason an entirely new nursery has been made at Highgate, where the head-quarters are situated, and this, with the extensive areas at Finchley and Barnet, comprise altogether well over two hundred acres. The Highgate nursery is to form a sort of show-place for the many kinds of plants raised at the other nurseries, though in the extensive glass-houses there a great many plants are raised and grown on to perfection. The extensive seed and bulb business is also conducted here under the personal supervision of Mr. Leonard Cutbush. Outdoors we found representative collections of Ivies (some 18 feet high), Clematises, Jasmynes, Ampelopsis, variegated Elms and other trees, Wistarias in pots (both the ordinary sinensis and the newer, long-racemed multijuga), some fine plants of *Crinodendron Hookeri*, and a fine collection of weeping standard and other Roses. In addition, there was a wonderful lot of clipped Boxes and Yews and Bay trees in tubs, for which the firm have long been famed and for which they find there is an increasing demand, this seeming to indicate that there is a tendency to revert, to some extent at least, to the formal gardening of bygone days.

In the glass-houses we were particularly interested in the winter-flowering Begonias that were just beginning to flower. The value of these plants in the conservatory during the winter months is not yet properly appreciated in many private gardens, though it is difficult to understand how anyone can afford to be without them. In addition to those of the Gloire de Lorraine type, a fine example of which is Lady Waterlow, with large, ivory white flowers, Messrs. Cutbush had a very good stock of the newer winter-flowering tuberous-rooted kinds, of which Winter Cheer is perhaps the best-known example. For a comparatively small outlay on these flowering plants a conservatory could be transformed into a delightful retreat of soft colour harmonies that could not fail to dispel the gloom of winter in the most benighted districts. Bedding plants of all kinds, including a fine new Ivy-leaved Geranium named Radiance, with vivid scarlet flowers; standard and bush Heliotropes, Hydrangeas by the thousand, retarded Lilies, Spiraeas, Lily of the Valley, Azalea mollis and Lilacs, and the variegated Bouganvillea F. K. Harris, which has beautifully variegated foliage but flowers like the ordinary kinds, were a few of the many good things that we noticed. In addition, there were several large houses devoted to Palms, and we were interested to see a splendid lot of Phoenix Roebelinii, which is about the best Palm of all for growing in an ordinary dwelling-house. As all the Palms and Aspidistras at Highgate are grown under as cool conditions as

possible, they are very hardy, and therefore more useful for decorating and house furnishing.

The glass-houses at the Finchley nurseries are mostly devoted to Perpetual-flowering Carnations, and on the occasion of our visit many beautiful varieties were in full flower and the plants in perfect health. A number of good new varieties have been raised here, one of the best being Mrs. Lucy McKinnon, a large-flowered and fragrant scarlet variety and the most brilliant of its colour that we have seen. Lady Ingestre, deep salmon pink, for which Messrs. Cutbush obtained an award of merit from the Royal Horticultural Society a year or two ago; Countess of Bradford, yellow, with rose markings; Countess of Onslow, heliotrope, with rose flakes; Jessica, white, with scarlet stripes, very fragrant; Marchioness of Tweeddale, deep pink; William H. Cutbush, scarlet; and White City, a good white, are others that have been raised at Finchley. In addition, the firm have all the other good standard varieties and novelties. Perpetual-flowering Malmaison Carnations have also come in for attention, and several good ones have been raised, notably King George, scarlet; Lady Miller, flesh pink; and Viscountess Goschen, dark rose. These have flowers resembling in size and form those of the true Malmaisons, with the perpetual-flowering properties of the smaller-flowered perpetual or winter-flowering kinds; hence they are a particularly useful and much-appreciated race. Of border Carnations we noticed some particularly strong young plants, many of which were ready for despatching to customers in all parts of Europe. Herbaceous plants of all kinds, including some very fine Michaelmas Daisies and Peonies, and an extensive stock of all the best alpine find a happy home at these Finchley nurseries, until repeated orders have exhausted those available for customers.

At the very extensive Barnet nurseries, where Mr. William Cutbush keeps a personal eye on them, Roses, ornamental evergreen and deciduous shrubs and trees, and fruit trees form the main features, though there are many what one might term sidelines of considerable interest. For instance, Violas are propagated here by the thousand, and Mr. Cutbush has for some years been personally working up particularly good strains of Pentstemons and Antirrhinums, flowers which he confidently believes will before long occupy much more prominent positions in our gardens than they do at present. Then there are Sweet Violets galore, while in the glass-houses we were particularly pleased to find some thousands of well-grown Ericas or Heaths for conservatory decoration. Pot Roses, too, were there in abundance, and for ten months in a year the firm are prepared to supply flowering Roses in pots. Outdoors we were much interested in some particularly fine Rambler Roses in pots ready for forcing. Many of these had sturdy rods over twenty feet long, which augured well for the display of flowers when the plants have been subjected to the proper temperature. Of ordinary bush and standard Roses in the nurseries the firm have some 230,000, these embracing all the best and most up-to-date varieties, including some particularly fine Dwarf Polyanthas. Fruit trees were there in enormous quantities, trained examples of all kinds calling for special comment. Lack of space will not allow us to go into details of these, but we may say in passing that all were in perfect health and well ripened, so that they should do well when transferred to their permanent quarters. This also applies to the ornamental trees and shrubs,

of which, in addition to the ordinary nursery stock, Messrs. Cutbush have some extra fine specimens that would be ideal where an immediate effect was desired.

ANSWERS TO CORRESPONDENTS.

FLOWER GARDEN.

PERENNIAL ASTERS (*Arundel*).—Michaelmas Daisies may be planted now or at any time while the weather is open up to the middle of December, or in mid-February to the end of March, without danger of loss. Climax is one of the largest-flowered forms. Mrs. Rayner, Ryecroft Purple and Ryecroft Pink, Moonlight, and Amellus varieties would all probably suit your purpose.

BORDER CARNATIONS (*Southern Scotland*).—In these high positions of Scotland, especially where the soil is good, the best layers to obtain are those that have been specially hardened, that is to say, grown in a highly-ventilated house. When layered, and after rooting moved from a cold frame to the open air, they seem to grow with remarkable vigour after this treatment in any part of Scotland. One Southern grower who makes a speciality of this method is Mr. James Douglas, Carnation specialist, Great Bookham, Surrey. A list of those varieties that have proved the best for Scotland is appended: Mrs. Andrew Brotherton, mode carmine, spotted white; Mrs. Elliot Douglas, yellow self; Montrose, white, marked scarlet; Robert Bruce, apricot; Renown, buff ground, suffused scarlet; Kate Nickleby, white self; Annie Laurie, bluish pink; Jasato, crimson; Rosy Morn, rose pink; Bookham White, white self; E. Schiffer, orange self; and The Bride, white, marked rosy scarlet. All of these have received first-class certificates from the Royal Horticultural Society, and all have been tested for some years and found to be the hardest of their race.

THE GREENHOUSE.

CHRYSANTHEMUMS: SYSTEM OF POINTING BLOOMS (*B. C.*).—There is no rule as regards pointing large show blooms at the National Chrysanthemum Society's shows. To the best of our knowledge and belief, boards of blooms are pointed only when the difference between certain exhibits cannot be determined by a superficial inspection of the blooms. Generally speaking, four or six points is the maximum obtainable for any one bloom, and the points considered are size, colour, form and freshness. As regards size, both depth and breadth are taken into consideration. Blooms having these points well represented are sure to score.

LARGE SPECIMENS OF VARIEGATED ALOES (*C. G. O. B.*).—Your variegated Aloes, or *Azaves* as they are correctly named, doubtless require repotting. Such plants often do quite well in the same pots for a period of from five to ten years. The older the plants are, the longer they may be left in the same pots, that is, providing they are fed regularly with manure-water. The repotting may be attended to in February, using a compost of good, fertile loam, broken up into cool-sized pieces, with a fair addition of small pieces of sandstone or old mortar rubble and sand. A pound or so of half-inch bones may also be added to the soil. Drain the new pots or tubs well, and work the new soil firmly about the old balls. The second growth of which you speak should be removed if it can be done without injuring the plant to which it is attached. That and any suckers may be potted and treated as young plants.

FRUIT GARDEN.

SILVER-LEAF ON PLUM TREE (*Arundel*).—The Victoria Plum is affected with silver-leaf disease. This disease is due to a fungus (*Stereum purpureum*), which gets into the plant by a wound. Trees affected rarely recover, and we recommend you to remove the tree at once and replant this autumn with a healthy tree.

SMALL RED EGGS ON FRUIT TREES (*T. C. C.*).—The eggs are those of the mite *Oribata lapidaria*. These mites, which are little larger than their eggs and of a slightly darker red, are very common on Apple trees. They are quite harmless, and are, indeed, likely to be beneficial, for they eat the spores of lichens and fungi.

BITTER-PIT IN APPLES (*J. R.*).—The fruit is attacked by bitter-pit, a fungoid pest that is very troublesome over most parts of the country. We would suggest spraying the trees while dormant with half an ounce of sulphide of potassium dissolved in a gallon of water, and next year, when the fruit is half-grown, with a quarter of an ounce of sulphide of potassium to a gallon of water.

SUMMER AND AUTUMN FRUITING RASPBERRIES (*Silly Gardener*).—It is quite right to say that ordinary summer-fruited Raspberries, if cut down to the ground in winter, will bear a crop of fruit in the autumn on the canes of next year's growth; but they will not produce such heavy or satisfactory crops as will the autumn-bearing Raspberries proper. Where, then, does the advantage come in of pruning them in this way? If you do not want summer Raspberries, then plant autumn-bearing varieties only. There are some grand varieties of these to be had now.

MOULDY SPOTS ON GRAPES (*A. J. P.*).—The Grapes are dead ripe and the spots indicate natural decay. They also show that the air of the house is too cold and moist. Apply a little heat to the pipes and keep the house perfectly dry. Give air freely on fine days and a little at night as well. There will appear no more spots then, and the Grapes will keep in good condition for another month or six weeks.

TO STORE WALNUTS FOR WINTER USE (*Tweed-side*).—We have tried many ways, and found the following to be the best: Put down a layer of slightly-moistened sand half an inch deep on the bottom of a box, packing-case, or anything of the sort available, place on this a layer of Walnuts and then a layer of sand, and so on until the box is full. We have found the Walnuts to remain in a good condition longer when the boxes are kept in a fairly dry room and not too cold.

PEACH FOLIAGE GOING WRONG (*J. D., Devon*).—The Peach foliage is damaged by the black thrips. Fumigate the house on two occasions, with an interval of about three days between, with one of the nicotine fumigants, taking care that the work is done after dark. The fumigation may spot the Grapes unless their skin is quite hard, and the fumes may prove harmful to persons eating the Grapes if they are used soon after. It would, therefore, be well to remove them before the fumigation is done. The Cherry is attacked by the boring moth larva, called *Senasia wool-borana*. This is a difficult pest to deal with, but you will find that smearing the trees in May with a mixture of clay and lime will tend to prevent the moths laying their eggs.

MISCELLANEOUS.

CELERY DISEASED (*E. C.*).—The Celery is attacked by the leaf-spot fungus, *Septoria Petroselinii* Ait. It is too late to effect a cure. The disease is carried in the seed, and is to be found on the plants from May onwards, when spraying with Bordeaux mixture should begin.

WIREWORMS (*J. B.*).—No measure is so effective as constant cultivation in ridding the soil of wireworms. Your experience with the soil fumigant is similar to that of many others, and if you cannot for any reason hoe frequently and dig often, we recommend you to trap the pests by burying pieces of Potato or Carrot near their haunts, marking the position of the pieces and examining them frequently.

CARNATION SPOT FUNGUS (*Anxious*).—The Carnations are attacked by the Carnation spot fungus, *Heterosporium echinulatum*. This fungus is always more prevalent when the air is damp, and we recommend you to plant the Carnations in a place where the air has free circulation, and to spray them, after removing the damaged leaves, with a solution of potassium sulphide, 1oz. to three gallons of water.

TREATMENT FOR OLD LAWNS (*H. K.*).—You may apply a dressing of well-decayed stable manure to your lawn at once, with good results, and in spring a dressing of bone-meal would do good. The manure should be worked about well in order that the grass may grow through it easily, and the bone-meal should be applied during damp weather. Soot and wood-ashes are also useful, but the latter encourages the growth of Clover.

CATERPILLARS TO NAME (*Cottingham*).—The grub sent is the larva of the garden swift moth. The grubs feed on fleshy roots of all kinds, and are very partial to bulbs and Peonies. Birds eat them greedily when they are turned out from the soil, otherwise they are difficult to deal with. Carbon bisulphide may be injected into the soil, poured into holes near the hiding-places, half an ounce in each hole, made by a stick to a depth of about nine inches. The moths fit over the beds at dusk in June, and may be captured by means of a butterfly net.

GRUBS IN GARDEN SOIL (*E. E. B.*).—The grub sent is the larva of the cockchafer. We recommend you to turn the ground up well and expose the grubs, which will be eagerly devoured by the larger birds. Rooks and gulls are very fond of them, and starlings will eat them. The ground in which plants are growing may be treated by injecting half an ounce of carbon bisulphide to the square yard. The fumes of this substance are deadly to annual-life (it is an excellent thing to use in killing wasps before digging out the nests), and does not injure the roots of plants.

VASES AND BOWLS FOR TABLE DECORATION (*M. C. B.*).—There is no golden rule as to the kind of vase or bowl that should be used in a table decoration, and we are not aware of there being anything new in receptacles of late. A bowl of glass or silverware of medium size should answer well for the centre of the table, and four small vases—one at each corner of the table—will be quite sufficient for a table of the dimensions you give. A tall glass bowl would be too big for a small table. Epergnes have gone out of fashion with those who have a true artistic temperament. Chrysanthemums of yellow and rich orange, with just a light dusting of bright crimson, are always most effective by day and night. Use in association autumnal and light green greenhouse foliage. Avoid crowding, and let each flower speak for itself.

NAMES OF FRUIT.—*G. W.*—Christmas Pearmain.—*G. C.*—1 and 2, Afriston; 3, Waltham Abbey Seedling; 4, Wellington; 5, New Hawthornden; 6, Hoary Morning.—*M. W. M. B.*—1, Queen Caroline; 2, Warner's King.

NAMES OF PLANTS.—*J. E. L.*—*Aster diffusus* horizontalis and *Polystichum vacinifolium*.—*D. K. S.*—1, *Corus sanguinea variegata*; 2, *Cassia fulvida*; 3, *Olearia macrodonta*; 4, *Cotoneaster frigida*; 5, *Arbutus Unedo*; 6, *Garrya elliptica*.

EDITORIAL NOTICES.

Every department of horticulture is represented in **THE GARDEN**, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in **THE GARDEN** will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

NOTES OF THE WEEK.

The Cape Gooseberry in Scotland.—Fruits of the Cape Gooseberry, *Physalis edulis*, have been offered in the Edinburgh Market and have met with a ready sale.

Draining Gardens.—Very fortunate is anyone who has a garden well drained, and at the same time possesses sufficient depth of soil to suit his crops. Any drains that require renewing or repairing should be commenced now, as it gives the disturbed soil time to settle again before the spring; 3 feet 6 inches deep should be a minimum, as gardens, particularly those for vegetables, are cultivated to a good depth.

The Use of Fallen Leaves.—It is very important that as many leaves as possible should be collected, particularly those of Oak and Beech, taking care to pick out sticks, stones and weeds. Stack them in low heaps where only moderate fermentation will take place. These leaves are excellent material for making hot-beds, and also for potting purposes next season, as leaf-mould is an important ingredient in most potting composts for the encouragement of root action, besides possessing considerable nutritive value.

The Value of Sweet Briars.—The Sweet Briar is receiving much more attention than it did at one time, owing, no doubt, to the many beautiful forms of Lord Penzance's hybrids from which to select. For hedges, particularly where space permits them to more or less ramble at leisure, they have a very attractive and natural appearance, and might well replace some of the old, rough hedges that often exist near gardens. Apart from their beautiful flowers and fragrant scent, their bright hedges, which are generally borne in great profusion, are a source of beauty the whole winter through, particularly in such places as the wild garden.

Lily of the Valley.—This is the month when permanent beds should be thoroughly cleaned over and a light dressing of leaf-soil and manure given, just sufficient to cover the surface of the soil. Old clumps may with advantage be lifted and replanted, and, if necessary, a good many of the best crowns be selected for forcing. The ground, where fresh beds are to be made, should be deeply dug and richly manured, and if it is in partial shade, so much the better. Plant the crowns just under the surface in rows 4 inches to 6 inches apart, making the beds about four feet wide. In this way the flowers are easy to gather.

A Rare Indian Lily.—Having been apparently lost to cultivation for some few years, it is interesting to record the flowering of *Lilium wallichianum* in the greenhouse at Kew. It has a fairly long tunnel-shaped flower, white inside, with dark purple markings on the exterior. In a wild state Wallich's Lily is said to be vigorous in growth, but in this country plants 2 feet to 3 feet high, bearing one flower, are the rule rather than the exception. Though found at fairly high elevations

in the Himalayas, except in a few favoured spots in the South and West this Lily is only suitable for cultivation under glass, either in pots or planted out in a border with *L. sulphureum*.

The Christmas Daisy.—This beautiful plant, *Aster grandiflorus*, is practically the last of the family, and, unfortunately, it only comes to perfection outside during mild autumns. It is one of the best, and is well worth growing. Coming as it does after all the others are over renders it all the more valuable, as may be realised this year in those places where it has been able to bloom in all its loveliness. It makes a very useful pot plant; in fact, it is the most reliable way of obtaining its blooms. The blue flowers look very effective when mixed with *Chrysanthemums*.

Nerine flexuosa alba.—All the Neries are useful subjects for the cool greenhouse, but none of them is more attractive than the white Zigzag Nerine (*Nerine flexuosa alba*), with its snowy white flowers, the petals of which are elegantly undulated and recurved. A batch of this choice, free-flowering plant intermixed with other Neries, particularly the large rosy pink *N. Bowdenii* or similar plants, will add greatly to the beauty of the greenhouse. Like all others of the genus, it must be well ripened in the summer by placing the plants in a dry place in full sun and withholding water from the time the leaves die till the flower-scapes appear, when they may be repotted or top-dressed.

The South African Kaffir Lily.—Though perhaps more frequently grown in pots for the decoration of the cool greenhouse, the Kaffir Lily (*Schizostylis coccinea*) grows and flowers more freely on a warm border outside. A sunny south border at the foot of a wall or greenhouse, such a place as one chooses for the Belladonna Lily, just suits it. If not well drained, 15 inches of the soil should be taken out, and some broken bricks or clinkers put in for drainage. In a soil consisting of fibrous loam, leaf-mould and coarse sand, the bulbs grow and flower freely. Flowering in October and November, it is particularly valuable, more especially from the fact that when cut the blooms last well in water.

Erica gracilis for the Greenhouse.—This pretty South African Heath is one of the few species which remain to remind us of a class of greenhouse plants which were in our grandfathers' days considered to be among the most decorative of indoor plants, and the supreme test of a gardener's skill to produce them in good condition. It is usually grown in large quantities in a few market establishments, and from those places the general trade is supplied. The plants as we usually see them are grown in 5-inch pots, and they form charming little bushes 9 inches to 15 inches high, made up of eight or nine main and numerous side branches, which, from early autumn until Christmas or later, are covered with small, bell-shaped, pink or white blossoms, according to the variety.

CORRESPONDENCE.

The Editor is not responsible for the opinions expressed by correspondents.)

Autumn-Fruiting Raspberries.—These are still bearing fruit here. We have had a grand crop throughout the past three months, the fruits being remarkably large and of good flavour. The canes are cut down in the early spring to within a few inches of the ground, fruit being borne on the current year's growth.—ELEANOR G. SHELLEY, *Avington Park, Alresford, Hants.*

The Mild Autumn in Ross-shire.—From the beginning of July we have been favoured with one of the best seasons known here for years. Bedding plants did wonderfully well, and it may interest readers to know that Begonias were in full bloom up till October 28, some even flowering on November 8. Dahlias, too, have given us their full share, and early Chrysanthemums are still to be obtained out of doors.—ALEXANDER ROSS, *Courthill, Lochcarron.*

Cyclamen ibericum.—This plant has been grown here for a good number of years, and last year was the first time that we recorded it as being in flower before Christmas, stray flowers appearing here and there before that date. This year its precocity is even more striking, quite a number of the plants being in full and luxuriant bloom at this date (November 19), while *C. neapolitanum* has still a flower or two left. I should think it is unusual for the flowering periods of the two species named thus to overlap.—F. H. C., *Rye.*

Hardiness of *Dracæna australis*.—The notes by "T. C. F. M.," page 570 of THE GARDEN for November 15, on the above plant are interesting. Here it is quite hardy, and receives no protection in winter whatever. *Araba Sieboldii*, *Hydrangea Hortensis*, *Camellias* of sorts, *Fuchsias* and *Azalea indica* also stand the winter unprotected. The last named make fine plants and are studded with bloom. At Penrhyn Gardens *Lapagerias* and *Oleanders* are growing outside on walls, and stand the winters well.—J. S. HIGGINS, *Glynllifon Gardens, Carnarvon.*

Dasyliiron Flowering Outdoors.—I am sending you a photograph of *Dasyliiron gracilis* growing in the gardens of The Cottage, Portlock Weir, a residence of Mr. G. W. W. Blathwayt. It was planted in November, 1906, and last summer threw up a very fine flower-spike 12 feet high. The bushes at the back are fine examples of the small-leaved Myrtle. It may interest your readers to know that in this favoured spot, on the coast adjoining North Devon, this greenhouse evergreen is thriving so well out of doors, as also are a great many choice and tender flowering shrubs and plants.—R. H. LEGG, *Melksham House Gardens, Wilts.*

Primula Poissoni Flowering Late.—I can fully corroborate every word that Mr. Blake of Clandon Park says on page 570 of November 15 issue concerning the merits of *Primula Poissoni*. It is still in full flower with me, and, though of a colour which not even an enthusiast could avoid associating with magenta, does not suffer in consequence thereof by reason of its late-flowering propensity, which enables it to escape the risk of clashing with other subjects. May I further suggest, in reference to an enquiry as to a suitable plant for massing under trees, that *Saxifraga umbrosa*, or *London Pride*, is infinitely preferable to *Ground Ivy*, which was put forward in answer to the query. There are few things to excel the

delicate pink, foamy masses of the blossoms of the *Saxifraga* when planted in large groups or as a continuous edging.—RAYMOND E. NEGUS, *The Lawn, Walton-on-Thames.*

The Persian Cyclamen as a Biennial.—I am obliged by the courteous letters of Mr. Brotherston and Mr. Willie (see page 558) relating to a previous article of mine on this subject. Like Mr. Brotherston, I am aware that very good results are to be had with old bulbs by some growers, and many and varied are the methods of culture advocated by successful cultivators. While I am quite willing to admit that my treatment of these two year old bulbs may in some respects be incorrect, I could easily retort that Mr. Brotherston's treatment of the plants the first year cannot be altogether right when the older bulbs give the finer flowers. The fact is, no one seems to be able to exactly

DASYLIIRON GRACILIS FLOWERING IN THE OPEN AT THE COTTAGE, PORTLOCK WEIR.

state what the correct treatment should be to ensure first-rate results. Some months ago a correspondent of THE GARDEN advanced what was to me the most original idea on the subject, so that I determined to give it a trial. Briefly, his advice was to shake the bulbs quite free of soil immediately they had finished flowering, and at the same time to pull off the entire foliage and re-pot, using as small pots as it was possible to get the roots into. I was so struck with the idea that I experimented with a dozen good bulbs, and with very fair results. With a few other plants I somewhat modified the treatment, merely pulling off the foliage and then top-dressing with fresh, rich soil. The results here are particularly promising, the foliage being very large and healthy, while the crowns are fairly bristling with flower-buds. Talking of old *Cyclamen* bulbs, I may say that the late James Walker, gardener at

Rivals Green, Lamlithgow, grew the largest and most profusely-bloomed plants I have ever seen. In many cases they were at least 2½ feet across, and carried quite 200 flowers. The blooms were small, but very finely coloured. These bulbs were at least ten years old. Mr. Walker, a very able, all-round gardener, could make nothing of seedlings, and yet he never failed with the old plants. Who can explain this? How do Mr. Willie and Mr. Brotherston measure a *Cyclamen* flower? To me a flower 6 inches across seems enormous, and, incidentally, undesirable, unless they measure by stretching the bloom flat. I do not admire the "spidery" type.—C. BLAIR, *Preston House, Lamlithgow.*

Gentiana verna.—We are all, I think, indebted to Mr. R. A. Malby for his interesting experiments with *Gentiana verna* (page 548, issue November 1), and his record of the results obtained by plants under and without a glass covering will be helpful to many who are struggling with this charming *Gentian*, but who have hitherto failed. This question of winter covering is a most important one, and it is only by such experiments as those of Mr. Malby, when conducted over a series of years, that several points regarding the cultivation of certain flowers can be elucidated. I hope Mr. Malby is continuing the treatment of *G. verna* adopted last season, and I would suggest that this winter he should cover the plant left uncovered last winter, and leave the other without the glass for this season. The longer ones grows alpines, the less inclined is one to generalise and dogmatise. *Campanula pulla* (of which I shall have more to say at another time) is a case in point. To return to *Gentiana verna*, Mr. Malby is to be congratulated on his success, and it would help us to understand it better if he could give us the size of the plants when planted and that they have now attained. His success is very great, and many will almost envy him the charming display his plants must have presented last spring. I do not think, however, the main trouble with *G. verna* is its shy flowering, but its difficulty of cultivation, as in many gardens it is difficult to establish, and requires some attention to induce it to grow. We are, I think, often too generous in our treatment of this plant. It does not always do well in a rich soil, and I find that one of a somewhat stony character suits it best, especially when it is thinly "mulched" with small stones or gravel. This mulching has been found of great benefit in gardens where *G. verna* could not be grown when attempted without it. The glass covering is, it is probable, highly beneficial to the flowering of this lovely plant, and if Mr. Malby will only continue his experiments, I am confident that he will deserve well of other alpinists. We know that certain other plants, such as the *Soldanellas*, for example, flower best if they have been covered with glass during winter. We know, however, that a foot or 2 feet of position may cause one plant to bloom better than another, and I have two little clumps of *G. verna* about three feet from each other which behave quite differently, although there is nothing about the respective plants or their positions to suggest why this is. I shall at once endeavour to test Mr. Malby's suggestions by covering with glass the shy-flowering of the two plants. Should it bloom more freely, I shall be ever grateful to your correspondent for his note. I may add that both plants are from the same parent—a free-flowering specimen in a garden where it had done well for years. Other plants in the garden might be tested, but these two will afford a better means of comparison.—S. ARNOTT, *Dumfries.*

Heliotrope Mme. de Blouay. Although this Heliotrope cannot vie with such a variety as Lord Roberts in respect of brightness, being even rather paler than the common Heliotrope, *Heliotropium peruvianum*, it has much to recommend it for massing. It is the dwarfiest variety I have seen, and the trusses, which are borne in great profusion, are quite three times the size of the common Heliotrope, and it possesses in full measure the delightful aroma of the Cherry Pie.

Chrysanthemum Elegance.—I have not seen this variety in any price-list, so I do not know how the vendor classes it, but it is an October crimson single, although not of the Mary Anderson type. I saw a batch of it in October, and was much struck with its floriferous character and its rich crimson colour; it is of medium height. I think, with an autumn even approximating to the one just closing, it might do quite well out of doors, even in Scotland.—CALEDONIA.

A Little-Known Rose.—I have never seen in any of your lists of Roses one called Donarte de Elvira. I chose it by chance out of a list years ago, and everyone who sees it wants it. It is a salmony pink, growing in long sprays, with lovely foliage, and is constantly blooming. I am picking it every day now. I have grown it over "banisters," made of twisted twigs, up each side of some stone steps leading to the garden, and, of course, now one sees no foundation—nothing but Roses. It is a Rose that, if better known, would be grown by everyone.—MARION DUNNELL, *East Harling, Norfolk*.

Hybrids from *Primula obconica*.—Regarding the remarks in THE GARDEN for November 8, page 564, in connection with *P. obconica*, there is not, so far as I am aware, any hybrid in which that species figures as one parent. I have tried to cross it with *P. coekburniana*, *P. pulverulenta*, *P. cortusoides*, *P. capitata*, *P. Forbesii*, *P. frondosa*, *P. marginata*, *P. rosea*, *P. vulgaris*, *P. Veitchii* and *P. megaseifolia*. I have raised seedlings from the latter which was fertilised with *P. obconica*, but no sign of hybridity could be detected. These were "selfed," and the result was still *P. megaseifolia*. I once heard that a plant had been raised from these two species which was fairly intermediate between the parents, but I did not see the plant and cannot vouch for its accuracy. Perhaps other readers may have been more successful.—T. W. BRISCOE.

Hints about *Campanula patula*.—May I take exception to Mr. Arnott's note on *Campanula patula* in your issue of November 8, page 562? This *Campanula* is *never* coarse, but extremely elegant and graceful. It is beyond all question a biennial. Division as a method of increasing (as ordinarily understood) is quite impossible. It seeds itself freely in damp, shady situations. Its only fault (besides that of being biennial) is that its long, wiry stalks are not always strong enough to support the flowers; but this occurs because we move it from its natural habitat of the undergrowth and bushes, where it can be seen in some of our Herefordshire woods in wild profusion. Did I not know the plant well in its wild and cultivated state, I would not dare to take exception to such an authority as Mr. Arnott.—ERNEST BALLARD, *Colwall*.

FORTHCOMING EVENTS.

December 2.—Royal Horticultural Society's Exhibition. Perpetual-flowering Carnation Society's Exhibition at Vincent Square, Westminster (two days). Scottish Horticultural Association's Meeting.

THE FRUIT GARDEN.

THE BEST CHERRIES AND THEIR CULTIVATION.

FROM the days when Henry VIII. scoured the Continent for new fruits and the resulting finds were planted at Teynham, Kent has been famed for its Cherries. But even in this county their culture is localised to a large extent, and the reason for this will be found to be—chalk. Where there is an abundance of this mineral, there are Cherries flourishing. On the granite soils, such as are found, for example, in the West of England, it steadfastly refuses to grow. The lesson is obvious. This fruit is somewhat impatient of the knife, and therefore restricted forms such as espaliers are not advisable. Even the more natural fan-trained forms on walls should not be too strictly dealt with in regard to pruning. The best wall fruits I have seen were grown on trees the tortuous branches of which would shock those whose eye for symmetry is well developed, but at the same time please those who consider that the first duty of a fruit tree is to fruit. The pyramid form is suitable, if not pruned too hard, and especially for varieties of the Duke race, whose neat, upright habit takes them halfway to this form. Cordons also do well on walls if not too much encouraged with nitrogenous manure, and this advice, indeed, applies to all forms. In the early stages of growth stable manure should be strictly avoided, and potash and phosphatic manure should only be given, with, of course, lime, if this is not present in the soil, in fair quantity. The culture of this fruit under glass is not undertaken so often as it should be. To defeat spring frosts and, incidentally, the feathered tribes, this method is very desirable, and for those who have not eaten "under glass" fruit a revelation awaits them. As the cooking Plum is to the Green Gage, so are outdoor Cherries to the indoor ones.

The soft-fleshed Bigarreans, so unfit for the untender mercies of Covent Garden, only require to be better known to those whose idea of a Cherry is the indigestible, if profitable, Napoleon; and the black varieties, such as the Tartarian or Circassian, are found in the highest perfection under orchard-house culture. The varieties that can be recommended for quality are, in the yellow, Bigarreans, Frogmore, Elton and Governor Wood; in black varieties of this race, the Tartarian above-mentioned, Early Rivers and Waterloo; and the old St. Margaret's or Tradescant's Black Heart, a name which takes us back to the Duke race, whose refreshing acid flavour is acceptable to many palates, and are best represented by May Duke, Royal Duke and Archduke.

The Morello Cherry needs no recommendation. Its preference for a cool wall and its never-failing cropping qualities have won it a place in all gardener's hearts. Of similar flavour is the Kentish Red, a very distinct variety, which for cooking is quite unequalled. Cherry jam made of this variety will be the first sort to disappear from the pantry. Use half a pound of sugar to 1 lb. of fruit, and you have a preserve fit for the proverbial king. To sum up, the secret of Cherry-growing is to forget the knife and the manure-barrow, and remember the lime. It seems a pity that these fruits are not more extensively grown in many gardens where the soil and situation are well adapted for them. If the hints given above are acted upon, the trees ought not to give much trouble. E. A. BUNYARD.

THE FLOWER GARDEN.

THE NAMING OF TULIP BREAKS.

THIS is doubtless a most important question which needs definite settlement, and the Tulip trials organised for the next flowering season will afford a splendid opportunity for it. The Editor and Mr. Jacob are kind enough to honour me by asking my opinion, but I am sorry to say I do not think I have yet found the philosopher's stone. I trust Mr. Leak and Mr. Hugh Dickson have been more fortunate.

Let me first state that the system of naming a broken Tulip with the same name as the breeder cannot be maintained, either for the Rembrandt-originate from the Darwins or for any other class of flowers. It would lead to hopeless confusion, because the addition "feathered" or "variegated" or "broken" would not be generally used for the broken form. Several examples of trade varieties of early and Cottage Tulips prove the necessity of changing such names, e.g., a yellow and buff colour break from Cottage Maid was originally called Cottage Maid broken, but when it became more generally known and appreciated it was called Cottage Boy; the white colour break of Joost van Vondel, formerly known as Joost van Vondel white, has since been dedicated to Lady Boreel; the feathered form of La Merveille has got the name of L'Hermite.

The second point to consider is that, if a breeder breaks, it does not always do so in absolutely the same style. It is quite possible that Mr. Farncombe Sanders breaks into a boldly-flamed form in A's garden, into a feathered form with B, and into perhaps still a third style in C's nursery, or even in more than one form in the same garden. In such cases A, B and C are certainly each entitled to give distinct names to their breaks. The difficulty only arises if such breaks are absolutely the same, and in such cases only a nomenclature committee would be able to settle things satisfactorily.

If the break is of real merit, it will soon be shown before the Tulip committee, and become known under a well-established name. If others are fortunate enough to have got the same break, they will be glad to adopt this name. Breaks of inferior quality which originate in more places at the same time will not be propagated or will soon have to disappear. Even if they had got several names, the confusion would not be very serious.

I do not see a way to express the origin of the broken Tulip in its name. Some names may afford a chance of suggesting the relation between breeder and break, such as Cottage Maid and Cottage Boy among existing varieties, and Emperor and Empress, Castor and Pollux, Hera and Leander, &c., may do for coming varieties. But there is a limit to such names, and most of the breeders, and especially the Darwins, have already names which are not fit to choose appropriate names in this style for the breaks. In most cases the breaks will, therefore, have names entirely independent from the breeders. This is a drawback, but the only way to avoid confusion. No name must be used for more than one variety, and the confusion will only be definitely settled when the same name is not found among early Tulips and Darwins, or any other section. ERNEST H. KRELAWE.

ROCK AND WATER GARDEN.

THE DESIGNING, CONSTRUCTION AND PLANTING OF ROCK GARDENS.

(Continued from page 584.)

AS I shall deal later with the arrangement of stone and planting, it is superfluous to go further into the development of the site here. I will, therefore, consider another site, quite distinct in many features, and one that is very common.

Sketch plan D shows a piece of waste land that has, in the development of other portions of the garden, been left over, more or less as a remnant. The land here is perfectly flat. As a termination to the series of gardens and lawns, a belt of shrubs has been planted, principally with a view to giving rather more seclusion to the gardens than is afforded by the woodland on the west. It was really a corner of a field used as a paddock, and as such was fenced in on both sides. One or two fine old Scots Pines suggested rock (Scots Pines always do, I think), and it was decided to turn it into a sort of rock garden. Further than this the ground offered no assistance towards design. No water could be introduced conveniently, and the surroundings were such that it would hardly have looked happy even had it been used. No one need be reminded of the picturesque association of Pines and rock. Some of our best artists, notably Leader and MacWhirter, have familiarised us with the scenes depicted by Scott in the following words:

Cast anchor in the rifted rock
And higher yet the Pine-tree hung—
His shattered trunk, and frequent flung
Where seemed the cliffs to meet on high
His boughs athwart the narrow'd sky.

As in the previous instance I have given, here also the first thing to ask ourselves is: "What arrangement does the site suggest? What are the links that will connect the scheme with the other portions of the garden without allowing the one feature to spoil the other by inharmonious

SKETCH E.—SCOTS PINES, ROCK AND HEATHER, SHOWING THE TREATMENT OF A PORTION OF PLAN D.

association, and, again, for what class of planting shall we arrange?"

With reference to the arrangement or design, we have two controlling factors, viz., there are no natural banks or slopes to help us, and there are three points (the three groups of Pines), and the surrounding margins of the site are fixed by the position of trees. My idea for this is to treat it rather as a bit of Heather moorland than as an alpine garden. Glacial deposits of stone in the forgotten ages will account for a considerable amount of a sort of "boulder" outcrop—scoriated and broken masses that rise here and there without anything of order or method in their positions. I have seen such in the open fields in parts of Oxfordshire; on the Purbeck Hills in the neigh-

bourhood of Swanage, and elsewhere. A slight undulating effect can be produced by creating depressions and mounds, not too pronounced, but all with some continuity of arrangement, so that shallow "valley" effects are produced.

The pathways should be the most emphasised of these valleys, giving the impression of being footpaths worn by the tread of ages, and should be so arranged that they create decided depressions in the neighbourhood of the Pines, as illustrated in sketch E. At the north and south ends any surplus earth may be deposited and planted with shrubs, so as to give a sense of enclosure, although sufficient openings should be left so that the view travels on naturally to any attractive features in the surrounding country. Semi-seclusion without any feeling of contraction should be the aim.

By comparing the two drawings D and E, a very fair idea of the scheme can be obtained. It will be seen that facile connection is made through the shrubs by introducing the pathways to and from the rock garden at the points where the access is easiest and nearest. In plan D, either in the original drawing or in reproduction, the path has become much too obtrusive; this must not occur on the land. Always remember that pathways should be subservient to, and not dominate, the general scheme. In connecting up the paths, due regard should be paid to the fact that it is unpleasant to be brought up short by a sudden twist or bend (a point not too carefully studied by many English landscape gardeners). The transition from one path to another should be easy. In France they have a useful expression that instantly conveys my meaning. If a proper connection of paths is made, they say it "goes." If the turn from one to another is abrupt or tortuous, it does not "go."

Colchester. GEORGE DILLISTONE.
(To be continued.)

PLAN D. SHOWING TREATMENT OF A PIECE OF WASTE LAND THAT CONTAINED SCOTS PINES AND JUTTING ROCKS

THE ROSE GARDEN.

IN A HAMPSHIRE GARDEN.

SOME OF THE NEWER ROSES.

(Continued from page 586.)

TEAS FOR EXHIBITION.

ONE would like, before referring in detail to exhibition Teas, to put in a plea for their more extended cultivation. They are, taken as a class, undoubtedly the freest flowering, extending over a longer period than any other section of the Rose. To-day (November 16) I cut over a hundred Roses for the house. A very large proportion of them were Teas. In no other class are the colours so exquisite and refined. They are admittedly a little tenderer and more susceptible to frosts than their cousins the Hybrid Teas and the Hybrid Perpetuals, but I believe they could be grown with ease in any garden south of the Thames; yet in how many gardens are they almost entirely neglected. Some of the finest garden and bedding Roses we have are Teas, notably, *Mme. Antome Mari*. A bed of this variety here has never been without flowers since May, and is now quite full of flower and bud, good in all its forms, in the half-open bud stage an ideal button-hole, growth and contrast of foliage with flower are excellent. *Lady Hillingdon* is the best yellow Rose for the same purpose; *Mrs. Herbert Stevens*, the best white. It is only when we come to pinks and reds that the Teas fail us, perhaps; but I am wandering away from Teas for exhibition purposes, to which I must return. Exhibition Teas are not many in number, but they make up in quality what they lack in quantity, and newer exhibition Teas are scarcer still. The last half-dozen years have not produced a dozen varieties, so my tale will soon be told. In alphabetical order one starts with a real good one in

Alexander Hill Gray (Messrs. Alex. Dickson and Sons, 1911).—Named after the veteran Tea Rose grower and exhibitor. I consider this the finest yellow Tea in commerce at the present time.

It was awarded the gold medal of the National Rose Society as far back as 1908 at the autumn show, when the raisers had but a small stock of it, and we had to wait until 1911 before it was put on the market, so that it has only had two seasons in which to become known and grown. Despite this fact, it was more frequently exhibited at the National Rose Society's Show this year at the Royal Botanic Gardens than such old favourites as *The Bride*, *Catherine Mermet*, *Souv. d'Elise Vardon*, *Cleopatra*, *Mme. Hoste* and *Mme. Cusin*, to name half-a-dozen of the old stand-bys. Its colour may be described as deep lemon yellow, which intensifies as the flower ages; of good size and beautiful formation, with a high, pointed centre. It is almost at its best in the autumn, is fragrant, and was placed fourth in order of merit in Mr. Mawley's

Analysis of the new Teas. I venture to think it will quickly displace one, if not two, of those now in front of it; in fact, the trade growers did so place it, and they would know more about its qualities.

Miss Alice de Rothschild (Messrs. Alex. Dickson and Sons, 1910).—A very beautiful Rose, but not often large enough to find its way into an exhibition box. A good colour, very strong perfume, which is distinctly *Maréchal Niel* like, very free and continuous flowerer, and a good grower. Not subject to mildew.

Molly Sharman Crawford (Messrs. Alex. Dickson and Sons, 1908).—The finest exhibition white Tea (both *Mrs. Foley Hobbs* and *White Maman Cochet* are tinted) that we have, and also a most excellent bedding Rose, sharing the honours in this latter respect only with *Mrs. Herbert Stevens*. Delicate eau de nil white, which in the fully-expanded

flower is too old to exhibit) Tea for exhibition purposes in commerce. It, too, had more than one try before it secured the gold medal. I think it was staged three times. It secured the silver-gilt medal at the National Rose Society's Royal Botanic Gardens Show in 1910, was exhibited at the Salisbury Show in the same year, but the award was not increased, and secured the gold medal at the autumn show, mainly with the help of some smaller flowers, separately staged, that were cut from that year's grafts grown under glass. The colour is delicate ivory white, with a faintly picoteed edge to the petals, of a clear, bright pink, and a young flower is a very beautiful Rose in consequence. A good grower, fine constitution, producing many fine flowers on a single plant at the same time; sweetly scented. What more can one say? What one can do is another matter. I suggest to those who have not got it,

Order it at once from the raisers.

Mrs. Herbert Hawksworth

(Messrs. Alex. Dickson and Sons, 1912).—Too new to have yet been seen much on the show-bench except in the exhibits of the raisers. There it has been frequently shown in fine form throughout the season. I remember an exceptionally beautiful bloom of it at the Gloucester Show. Its massive, yet smooth, shell-like petals form a large, globular-shaped flower of great depth. It is almost a pure white that I am sure has a great future in front of it. It is the only Tea of last year's introduction that is likely to be of service to the exhibitor, and this year, so far as I am aware, the record will be a blank. It will be noted that all of these new Roses I have named are produced by Messrs. Alex. Dickson and Sons, and the lovers of Tea Roses owe them a great debt of gratitude. When one remembers that with the exception of *Mme. Constant Souper* we have not had an exhibition Tea from the Continent for more than ten years, it almost looks as if, without them, Tea Roses for exhibition purposes would cease to exist.

Mrs. Hubert Taylor (Messrs. Alex. Dickson and Sons, 1909).—

A fine, strong, healthy constitution, with very vigorous growth. A suggestion of pale pink on its petals is one of its distinctions.

A beautiful Rose, very free-flowering and, if disbudded, of exhibition standard. Supposed to be a *Mme. Cusin* seedling. It received the gold medal of the National Rose Society at the Luton Show in 1908, very much to the delight of Mr. Mawley I remember, after whose niece it is named.

Nita Weldon (Messrs. Alex. Dickson and Sons, 1909).—Another white Tea with a delicate flush. Sent out by the raisers as a decorative variety only, it has during the last two years been frequently exhibited, and was well represented at the "National" this year. It is a delightful Rose, round-shaped rather than pointed, very free-flowering and delicately perfumed. A good grower.

Climbing Souv. de Pierre Notting (Messrs. Frank Cant and Co., 1912).—All Tea exhibitors know how useful the type bearing this name is.

ROSE MRS. E. J. HOLLAND, A HYBRID-TEA WITH DEEP PINK FLOWERS. SUITABLE FOR GARDEN AND EXHIBITION PURPOSES.

flower becomes pure white. The flowers are of large size, well formed and held erect; sweetly scented. A very marked feature is the length of time a bloom will last on the plant, and also when cut. I have always had a great regard for this Rose since the first time I saw it in 1904 at Newtownards, and was very disappointed when it failed to obtain the gold medal. Its subsequent career has proved that it fully deserved it. I should put it in the first half-dozen exhibition Teas. It was more frequently exhibited, I see, than *Maman Cochet* at the "National" this year.

Mrs. Foley Hobbs (Messrs. Alex. Dickson and Sons, 1910).—If Molly Sharman Crawford can count on being in the first half-dozen, I am inclined to place this Rose at the head of the list as the most reliable (seldom does the split appear until the

PART OF THE SUNK GARDEN AND LILY POND AT HALLINGBURY PLACE.

I suggest they will find this form of it much more so. It bears larger flowers, of a better colour and shape, with less of the outer short, ragged petal that so often disfigures the type. A plant I had from the raisers last year has been very fine, and is now flowering from the laterals of the early wood of this year's growth. It is a rampant grower, and I can strongly recommend it, not only to exhibitors, but to garden lovers, as the best yellow climber in commerce.

HERBERT F. MOLYNEUX

Southampton.

(To be continued.)

GARDENS OF TO-DAY

HALLINGBURY PLACE, BISHOP'S STORTFORD.

THE series of gardens at Hallingbury Place are particularly fine examples of what can be done in a comparatively short time, providing natural facilities, such as are to be found there, exist. When about three years ago Mrs. Lockett Agnew, whose charming home this is, decided to remodel the whole place, few of the beautiful features to be found there now were in existence; yet at the time of our visit, during the closing days of May, the whole were so well finished as to give one the impression that they had been there for quite a long period. As already indicated, the surroundings of Hallingbury Place consist of a unique series of gardens, each complete in itself, but each leading naturally and connectedly to the next.

The Sunk Garden and Lily Pond.—Turning to the left, one enters through

an unobtrusive but elegantly wrought iron gate, cunningly inserted between two tall English Yews, to a path bordered by tall Yew hedges. At about halfway along this path, at a point where it turns sharply to the right, the stranger involuntarily pauses in surprised admiration of the picture that breaks on his or her view. Stretching out at their feet is a long, formal Lily pond bespangled with

if this were all there was to note about this garden, the effect would be charming enough; but it is not. The designer conceived the happy idea of sinking the whole some 2 feet and retaining the banks, with a dry wall so arranged that a magnificent collection of alpines and trailing plants could be introduced, and at the same time providing a sort of panoramic view of the gardens as seen

the choicest *Nymphaeas* in white, crimson, pink and cream varieties. The pond itself broadens out in the foreground into a square pool, and was designed specially with a view to obtaining the best possible perspective effect. On either side of the square pool rise two simple jets of water that, rising well above the eye-level, meet in a sort of arch of water that focusses the view down the long canal. The bed design is very simple, being merely rectangular borders running close up to the coping of the pond on either side, but by a skilful arrangement of the planting the most exquisite colour effects are obtained. This varies somewhat from season to season, that for 1913 being as follows: Three sides of the beds are edged with *Nepeta Mussini* and *Cerastium tomentosum*. The fourth (or pond) side is grouped with pale blue *Linum narbonneuse*, *Iris sibirica*, and a few grassy plants, such as *Eulalia japonica gracillima*, &c. Each bed also contains two masses of a dwarf Rosemary, the remainder being filled in with Ivy-leaved *Pelargonium Gahilée*. By this combination a delicious lavender and pink effect is obtained. Even

PERGOLA IN THE ROSE GARDEN, WITH MADONNA LILIES, AND A BED OF *NEPETA MUSSINII* IN THE DISTANCE.

from the approach. At the base of the wall garden runs a path surrounding the four sides, approached at either end down steps through the wall. Between this path and the beds a just proportion of grassy lawn is introduced, while surrounding the whole garden are broad grass walks that provide just that note of peace and rest so desirable in any garden, and so frequently missing when any attempt at formal lines is introduced. The whole effect of the sunk garden is to lead the eye towards the woodland, and attract the stranger on and through it to see what lies beyond. In passing, however, one is compelled to notice the fine groupings of Foxgloves, Mulleins and other flowering hardy plants, grouped with real natural charm in the shadows. There is one other feature in the woodland that demands notice—a magnificent pair of giant Cedars; two of the finest we have ever seen, indeed. It is said of these two that some 450 years ago one of the ancestors of the present owners of the estate brought two cones from the Holy Land and planted them in this position, and that these trees are the result.

May-Flowering Tulips Massed for Colour Effect.—Passing on to the left, along a slightly-curved path, the visitor (if he happens to be there at the right season) opens a small wicket-gate, takes a few steps forward, and receives surprise No. 2. On the right, stretching away in every direction among the trees, are gorgeous masses of May-flowering and Darwin Tulips. The trees have been so thinned as to create long vistas, huge beds made in the grass, and the varieties so arranged that from all the principal points of view the colours form distinct and pleasing gradations or combinations. In the foreground are massed the stronger colours, such as Pride of Haarlem and Professor Rawenhoff, while in the extreme distance the paler lavender and lilac shades, such as Melicette and Erguste, are used.

The Rose Garden.—Continuing the walk, one passes through Yew hedges into the Rose garden. Everything on the estate, the house, walls and buildings, is of brick—brick that has taken on the tone of age, and that looks warm and rich in the Herts atmosphere. The pergola that extends the whole length of the Rose garden was therefore constructed of old brick, relieved with tile creasing at about every four courses. This has the effect of somewhat lightening the appearance of the pillars, and gives a sensation of design that, while looking in no way "fussy," certainly achieves the result of destroying the monotony of plain pillars. All the walks are paved just sufficiently wide to ensure dry walking during wet weather. One of the most charming features in the Rose garden is a long, straight walk, paved and bordered with Lavender. Rising above the Lavender are stout Fir poles about five feet high, on which climbing Roses are festooned from one to the other. Colour effects here, as everywhere else, have been carefully studied. Pale lavender blue Clematises mingle with pink Roses on the walls; pretty combinations of

pink and cream are used elsewhere, while here and there a mass of rich dark purple Clematis is mixed with just the right shade of crimson Roses. One could linger here and find much of interest for a considerable time, but there is much else that calls for attention. Stretching along the whole front line of the Rose garden are tennis and croquet lawns, approached by broad picturesque steps. Before the gardens, tennis courts, &c., were made, there was a sunk fence that extended right round the gardens, over half a mile in length. At this point the land has been sloped back to an easy gradient from the base of the wall and planted thickly with wickuriana and other free-growing Roses. Crevices have been made in the brickwork and filled with Antirrhinums, Aubrietias, Alyssums, Achilleas, Campanulas and numerous other plants suitable for wall culture, with an artistic effect that it is impossible to adequately describe.

boulders rise from masses of every known variety of alpine and rock plant, and every crevice and cranny is rich with some choice gem, while the stream and its banks become in the summer-time a miniature wilderness of aquatic and semi-aquatic life. Here, again, the art of concealment has been so carefully utilised that it is quite impossible to realise the existence of the rock garden until it actually breaks on the view. Returning by the opposite side of the pond, the visitor arrives again at the entrance to the Rose garden; but there is no need to go back that way.

The Wild Garden.—Straight on is a broad pathway, on the right of which is the wild spring garden. As, however, at the time of our visit this was past its best, we cannot speak authoritatively as to its effect, but the arrangement of its undulating walks, grassy banks and the remains of innumerable spring-flowering plants lead us

MAY-FLOWERING TULIPS GROUPED FOR COLOUR EFFECT UNDER APPLE TREES IN MRS. LOCKETT AGNEW'S GARDENS.

The Ornamental Pond and Rock Garden.—Leaving the Rose garden, through a very beautiful iron gate, one instinctively turns to the right, where a fine stretch of water meets the gaze. This is the "Morley" pond, believed to have been an old fish pond, and round which clings the romance of a ghost story. By the removal of some thousands of tons of earth, creating long, sloping valleys between giant Oaks right down to the water's edge, what was once a rectangular pond, bounded by gravel paths, has been transformed into a beautiful natural water garden, just sufficiently planted to give pleasing effects without overcrowding. Some irregular stepping-stones tempt the stranger on until, having traversed the length of the pond, one arrives at the rock garden. The overflow from the pond is taken through the rock garden in a sort of rocky stream. Great

to think that it possesses, when in flower, a charm all its own. Hastening on, one reaches a superb herbaceous border, and, pausing here and there to admire various effects therein, suddenly emerges into what is called the wild garden, where Art and Nature have combined to achieve one of the simplest, and yet most exquisite, garden pictures imaginable. Involuntarily, as one enters between the trees and catches glimpses of the riot of growth and flower in every direction, the words of Goldsmith's "Deserted Village" enter the mind:

Near yonder copse where once a garden smiled,
And still where many a garden flower grows wild,

Poppies, Pæonies, Lilioms, Broom, Lupines, Rose-mary, flowering shrubs of all descriptions, Azaleas, Briars, anything and everything have been pressed into service; nothing has been considered too good or too common if it was only beautiful and could

be made to grow. And we must here pay a tribute to the talented head-gardener, Mr. Heath, who by some extraordinary magical influence manages so to organise these delightful gardens that failures seem to be non-existent. We do not remember through the whole course of a pleasant day seeing one plant that did not speak eloquently of the care and attention bestowed, and yet the whole is maintained in its proper character.

Would space permit, there are a great many other interesting features at Hallingbury Place that we could write about, such as the beautiful Cedar avenue, the kitchen garden and glass-houses, and the old Mulberry tree planted in the time of James I. in obedience to the Royal Command to plant Mulberries for silkworms. The series of gardens, of which we give a few typical illustrations, have been designed and carried out by Messrs. R. Wallace and Co., under the supervision of Mr. George Dillstone, whose articles on rock garden construction we are now publishing. Mrs. Lockett Agnew, who is an ardent admirer of all that is beautiful in Nature, and particularly in gardening, has taken an enthusiastic interest in the making of these gardens.

GAS BOILERS FOR GREENHOUSE HEATING.

IDARESAY that many amateurs who, like myself, are away all day at business have avoided getting a greenhouse, or, if they have one, it is a cold house with no heating apparatus, owing to the trouble of attending to the fire. This is a very reasonable excuse, as it is no joke to come home after a long day at the office and go straight out to stoke a fire, nor is it the kind of work that one likes to ask those at home to do. I was in this predicament myself for some time, when I noticed a gas boiler advertised for heating a garage, and on making enquiries I found that there were several on the market suitable for heating greenhouses. I made up my mind then to get a greenhouse and try heating it with gas. I got a local man to build me a small greenhouse, and I then ordered the boiler and a suitable length of pipes, which arrived in due course. All were easily fitted together and a pipe connected with the meter in the house. On this pipe there are two cocks, one at the boiler and the other at the meter. The advantage of having the one at the meter is that during the summer, and when the heat is not wanted, the gas can be turned off here, and so prevent any possible waste by an escape in the pipe out to the boiler.

With the apparatus that I have, no fumes can possibly reach the plants, as the boiler is outside of the greenhouse, and is connected to the main pipes inside by two small pipes which pass through

the side of the greenhouse. A small iron lutch measuring about twenty inches square fits over the boiler, and so keeps it protected from the weather, but at the same time lets the fumes escape through a number of ventilation holes round its sides. The pipes, which are 4 inches in diameter, heat up in about an hour from the time the gas is turned on, and, when the desired heat is obtained, the gas can be turned down to a small peep just sufficient to keep the heat in the pipes. It will thus be seen that a very small quantity of gas is consumed, and, as gas is now so cheap everywhere, the cost is not great.

THE BRILLIANTLY COLOURED COLUMNNEA CÆRSTEDIANA FROM COSTA RICA. IT WAS DISCOVERED IN 1861, BUT LOST TO CULTIVATION UNTIL RECENTLY.

Any amateurs who have hitherto debarred themselves the pleasures of a greenhouse, owing to the time and trouble spent with the ordinary coke fire, should write to the makers of any of the advertised boilers and ask them for particulars. My own is a "Garajo," and I can confidently recommend this to anyone, as I have never had the slightest trouble with it, and the only attention it needs is an occasional brush over to remove any particles of dirt which the gas discharges. I have found it very economical, because if the nights are mild there is no necessity to have any artificial heat in the greenhouse at all, and should

the weather become suddenly cold, the heat can be turned on in a second. On dull, wet days it can be most successfully used to dry the atmosphere by turning on the gas for an hour or so. These boilers are sure to give satisfaction if kept in good condition, and the time and labour they save make them a boon to the amateur. G. B.

NEW AND RARE PLANTS.

FIRST-CLASS CERTIFICATE.

Columnnea cœrstediana.—A remarkably beautiful gesneraceous plant from Costa Rica. The species is of shrubby growth, the prostrate or trailing branches thickly set with small, ovate, shining leaves, from whose axils, on short footstalks, the 2-inch-long, tubular flowers issue. These latter are of the most brilliant colouring, almost orange scarlet, save for a touch of yellow colouring near the throat. The well-flowered example, illustrated on this page, was a great attraction. From Sir Trevor Lawrence, Bart., Dorking (gardener, Mr. Bain).

AWARDS OF MERIT.

Begonia Syros (B. socotrana crossed with a tuberous-rooted variety).—Quite a charming addition to winter-flowering Begonias, the compact habit and abundant flowering rendering it most attractive. The predominant colour shade is pink, with a suspicion of white at the edges. From Messrs. James Veitch and Sons, Chelsea.

Chrysanthemum Mary Morris.—A well-grown plant, some 4 feet high, of this single-flowered variety was shown, and a few such would be welcome in any conservatory at this season. The colour is deep terra-cotta, with reddish bronze. It is a very showy variety. From Mr. T. Stevenson, gardener to E. Mocatta, Esq., Addlestone, Surrey.

NEW ORCHIDS.

AWARDS OF MERIT.

The species and varieties to gain awards were of a varied nature. Lieutenant-Colonel Sir George Holford, K.C.V.O., showed a handsome *Cypripedium* named *Cyclops*. Messrs. Charlesworth and Co. gained awards for a grand variety of *Lælio-Cattleya* *Feronia* and for *Angraecum recurvum*, the latter an interesting species with comparatively small white flowers. Messrs. Flory and Black of Slough showed *Dendrobium leeanum* *Langley* Variety, while from Messrs. Armstrong and Brown came *Miltonoda Harwoodii* *The Shrubbery* Variety and *Cypripedium Kentore*, the latter an attractive variety possessing some of the characteristics of *C. fairreanum*, from which it is descended.

GARDENING FOR BEGINNERS.

FLOWERING SHRUBS FOR SMALL GARDENS.

THERE are now so many shrubs available for the outdoor garden that those who have little knowledge on the subject experience a difficulty in making up their minds which to choose; therefore the following list of twelve really good and showy kinds has been compiled as an aid to beginners who are about to make a selection for present planting. The peculiarities of each kind are dealt with briefly in the accompanying notes.

Hamamelis mollis.—This is the best of the Witch Hazels. It is a native of China, and is recognised by its large, broadly oval, hairy leaves and fragrant, golden flowers, which appear during December or January. The petals differ from those of other Witch Hazels by being flat with hooked ends, instead of twisted, as is usual in other kinds. It thrives in light, well-drained, loamy soil, to which a little peat has been added, and requires a light and open position. No other pruning is necessary except what is required to keep the plant in shape.

Ribes sanguineum atrovirens is a very rich coloured form of the ordinary Flowering Currant. When planted in good loamy soil it grows into a bush 4 feet or 5 feet high and as far across, and bears its rich red flowers freely during April. No regular pruning need be given, but if vigorous young shoots appear from about the base, it is a good plan to encourage them by removing one or two of the older branches.

Daphne Mezereum.—No plant is more popular than this when it is covered with its fragrant, red flowers in February. It is often met with as a shapely bush 2 feet to 2½ feet high. Cool, loamy soil containing a little lime suits it well. Towards the middle of the summer it is again showy by reason of its rich red fruits. It does not require pruning.

Spiræa arguta is, perhaps, the best of the early-flowering Spiræas. It is of hybrid origin and at its best during April. At that time every branch is laden with pure white blossoms. When planted in loamy soil it may be expected to grow at least 4 feet high, with a wide spread. The branchlets are slender and have a graceful poise. During the summer they carry dainty, light green leaves. It is only necessary to prune when the bushes are outgrowing their positions. The branches may then be cut back well as soon as the flowers fade.

Spiræa japonica Anthony Waterer belongs to the summer-flowering Spiræas. Growing about two feet high, it forms a shapely bush, and produces

large, flattened heads of bright red flowers freely over a period of several weeks during July and August. The best results are obtained by pruning the younger branches about halfway back each spring, and removing at the same time some of the older wood right to the base. Give rich, loamy soil and a sunny position.

Magnolia stellata.—Though this is one of the most beautiful of all flowering shrubs, it is only

itself on any object within reach, and the secondary branchlets hang in graceful fashion round about. A somewhat similar effect is produced when it is planted against a pillar or trellis, but when planted in a bed in the open ground and cut hard back to within a couple of feet of the soil each year after flowering, it forms strong, erect shoots 3 feet to 4 feet long, which blossom from base to summit. Any good garden soil is suitable.

Prunus japonica flore albo pleno.—This is a double white flowered form of a dwarf Cherry from China and Japan. It forms long, slender branches, which bear blossoms from almost every leaf-axil during April or May. Good, loamy soil must be provided, and some of the older wood be removed every second year to make way for young growth, for the more vigorous the young wood is, the greater is the number of flowers.

Diervilla Eva Rathke is one of the most beautiful of the many charming garden forms of the genus. Its rich crimson flowers are borne freely during the greater part of the summer. Plant in rich, loamy soil and remove a little of the older wood each year, allowing the young wood to remain its full length.

Viburnum tomentosum plicatum.—Few shrubs are more beautiful than this during June or early July, for at that period it is a mass of round flower-heads, the flowers being sterile and made up of large white bracts after the manner of our common Snow-ball Tree. It is a native of China, grows 5 feet high in loamy soil, and requires no pruning. A light and sunny position is desirable.

Viburnum Tinus.—This is the Laurustinus of Southern Europe and our gardens. Many people will doubtless be familiar with it, and those who do not already know it may gain a good idea of its beauty from the accompanying illustration. Its dark, evergreen leaves provide an excellent background for its waxy white flowers, which open at intervals from November to March. Ordinary garden soil suits it, but it must not be transplanted when large. No regular pruning is necessary.

Cytisus scoparius andreanus is a variety of the common Broom which differs from the type by having rich reddish brown wing petals. It may be grown almost anywhere, even in comparatively poor soil. Pruning must be practised each year as soon as the flowers fade, but the branches must not be cut back into wood which is older than one year. The blossoms appear in May.

In a future article I will name another dozen for those who require a wider selection. D.

VIBURNUM TINUS OR LAURUSTINUS, A BEAUTIFUL WINTER-FLOWERING SHRUB FOR SMALL AND LARGE GARDENS.

suitable for the milder parts of the country, for its glistening white, star-shaped flowers expand during early April and are sometimes injured by late frosts. Under favourable conditions it forms a shapely bush 6 feet to 12 feet high, and the branches are hidden beneath its wealth of flowers. Well-drained loamy soil with a little peat suits it well. It does not require pruning.

Forsythia suspensa is easily one of the best twelve flowering shrubs. A native of China, it forms a rather loose, graceful shrub 8 feet to 15 feet high, and bears a profusion of golden, bell-shaped flowers during April. Its character is altered according to the way in which it is grown. If allowed to grow freely, its main branches support

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Flower Garden.

Helleborus niger.—This beautiful midwinter flowering plant is in a forward condition this year, and to ensure having the blooms as free from marks and stains as possible, steps should be taken to cover them with lights. Before doing so all dead and decaying leaves should be cleared off the plants, and a good soaking of liquid manure may be given. The lights should be raised above the plants some 2 feet or 3 feet, so as to allow a current of air to pass over the plants, and thus keep them as dry as possible at this season. The practice of lifting the roots and placing them indoors is not to be recommended, as, by covering as advised, the flowers may be had quite as clean, and, further, there is no check to the plants. If lifted, they take at least two seasons to get over the check.

Solomon's Seal.—This ever-popular plant is very useful in the spring for cutting, and where grown in quantity, lifted clumps make good decorative subjects for the conservatory. To increase the stock, clumps should be lifted, replanting the individual crowns from 6 inches to 9 inches apart in rows.

Spiræas may now be lifted for forcing purposes, splitting up a portion of the plants and replanting for stock. These like a fairly sandy soil, and it should be liberally dressed with short manure. In planting, sufficient space should be allowed the plants to develop their foliage, without which it is impossible to secure good crowns.

Plants Under Glass.

Bulbs.—The several varieties of *Duc van Thol* Tulips should now be ready for introducing into heat; and after seeing with what success such subjects are handled by our market-growers, I am led to think that the majority of private gardeners give them too much light and not sufficient heat. The house or frame should be covered either with mats or tiffany till the flowers are well in evidence, when the plants should be given a little more light and air. A temperature of from 60° to 70° is necessary to get them fairly long in the stems, and at no time should they be allowed to become dry at the root. Frequent dampings overhead are essential.

Narcissi Van Sion and Golden Spur may also be brought in, but these will not stand quite so much heat as the Tulips. Other details of cultivation are similar.

Roman Hyacinths are now making a good show, and for use as pot plants they should be carefully staked. The later batches may be brought out of the cold frames, as it left there much longer the blooms will be inclined to damp.

Italian Hyacinths may be brought forward to succeed the Roman Hyacinths. These are particularly useful in January and February, both as pot plants and for cut flowers. The large-flowering varieties of Hyacinths generally are not ready for bringing forward, but the variety *La Tour de Auvergne* forces well, and I have frequently had it in good condition by Christmas and the New Year. Most of the early bulbs under ashes should be gone over, and those that have rooted well and made 2 inches or 3 inches of top growth may be removed to the cold frame, where they should be covered with mats for a few days to exclude the light, and ample protection must be provided against frost.

Cyclamen that are throwing up flowers must be well looked after in the way of water and manure, as just at this stage there is a great strain on the plants. I noted a very fine batch of these plants at the Paris Show, the foliage covering a space of at least 18 inches, while the flowers were equally good. The grower told me they were only one year old, and were grown in a moderately warm house all through. The difference between these and part of the same batch grown in frames was particularly noticeable; hence the deduction that the plants like a little warmth at the root, especially where early plants are desired.

The Kitchen Garden.

Seakale.—By this date Seakale should force fairly well, and batches should be introduced into the forcing-house or frame at intervals, according to the requirements of the establishment, though where limited quantities are to hand it may be

advisable to reserve them somewhat until the supply of outdoor vegetables is less plentiful.

Asparagus.—Further batches should be placed in the frames as required. A good hatch put in now should be ready for use about Christmas or the New Year, a time when choice vegetables are in great demand.

Mint should now be introduced into heat, and if this has been grown in boxes as advised in a calendar early in the year, it will be found to force much more quickly than roots freshly lifted from the open ground.

French Beans.—The supply of French Beans is about over in the cold frames, though where the pits are heated the plants may remain for a week or two longer. Batches that are coming along in pots must receive careful attention. They must not be allowed to get dry at the root, and frequent dampings between the pots should arrest any attacks from spider.

The Hardy Fruit Garden.

Transplanting Fruit Trees.—The weather up to now has kept very open, and the major portion of transplanting fruit trees should be completed. Where it is not finished, I would advise pushing the matter forward at once.

Bush Fruits.—Any contemplated additions in this department should also be put in hand. Well-trenched, though not heavily-manured ground is the best for bush fruits, and quite young bushes are preferable to those that may have been cut back three or four times.

The Cordon system of training Red and White Currants and Gooseberries is to be preferred to growing on the bush system. By this method excellent crops are obtained, and the ease with which they can be gathered should be a sufficient recommendation. I quite believe that a heavier crop can be obtained from a given area of ground by planting the rows of trees from 3 feet to 4 feet apart. In the case of Gooseberries for dessert purposes, it is infinitely better, the fruits being of a uniform quality, while those on bush trees are of varying degrees of quality, according to the light and air obtainable.

THOMAS STEVENSON.

(Head-gardener to E. Mocatta, Esq.)
Woburn Place Gardens, Addlestone, Surrey.

FOR NORTHERN GARDENS.

The Flower Garden.

Bedding Plants.—The stock of these will require careful attention for the next few weeks. Damp is the worst enemy at this season. Geraniums should be kept fairly dry, and, when watered, it ought to be done without a rose, so that no water may touch the foliage.

Flower-Stakes.—The stock of these should be overhauled during bad weather. In many cases where a stake is decayed at the base, a portion can be cut away and the stake repointed, when it will be fit for another class of plant. The ubiquitous Bamboo has well-nigh ousted all others, but those who have them at command should utilise Hazel and Elm suckers. Again, those who can on their own estate procure tops or thinnings of Larch or Spruce will find them, when dressed, very suitable for Dahlia and Hollyhock stakes, and when partially trimmed they are excellent for Sweet Pea clumps.

The Wall Garden.

Building.—The most natural and generally the most successful wall garden is that of the retaining wall style, the mass of soil behind conserving the moisture for the use of the occupants. Build the wall with a good deal of "batter"; in other words, the wall should not be perpendicular, but slope backwards. As the operation proceeds, work in some loamy soil behind and between the stones. Where plants are available, it will be found a good plan to plant them as the work proceeds, a proportion of the available spaces being left for subsequent planting or sowing. Another important point is that the individual stones, when being placed in position, should slope a little backwards, so that the rain falling on them will trickle towards the roots of the plants.

The Pleasure Grounds.

Turfing.—Any necessary turfing should be carried through during fine weather. Rough tufts

of grass often assert themselves on lawns, and sometimes there are spots where the rabbits frequently congregate. These should be cut out and some good turf substituted. Again, depressions occur in lawns from time to time. In such cases the turf should be cut into convenient breadths, rolled back, the depression made up with soil not richer than the mass below the lawn, and the turf rolled back and beaten firm and smooth.

Pruning Ornamental Trees.—I am not here referring to a general pruning, but Purple Beeches, Thorns, Laburnums, &c., often lose their contour for lack of a little timely attention in the way of pruning back any over-vigorous branches.

Plants Under Glass.

Plumbago rosea.—This is one of our most useful winter-flowering plants. Those in 5-inch pots will be benefited by bi-weekly mild doses of liquid manure. A temperature of 60° to 65° suits them admirably.

Coleus thyrsoides.—This plant will soon be showing its bright blue flowers. Meanwhile it should be pretty liberally fed. A warm greenhouse is all it wants in the way of temperature.

Lily of the Valley.—This is such a general favourite and is so easily manipulated that a batch of it should be introduced from time to time. Good retarded crowns are the most satisfactory. Plunge in some light material, which should never be allowed to become dry. Cover the pots with an inverted pot of the same size till the flower-spikes are quite 2 inches high. In a temperature of from 60° to 65° they will be ready in about three weeks.

Fruits Under Glass.

Sowing Early Tomatoes.—Where an early crop is desired, seed should be sown without delay. For this sowing some of the smaller, free-setting varieties, such as *Stirling Castle* or *Lister's Prolific*, will be found most suitable.

Starting the Early Peach-House.—Where there are two or more houses, one may now be started. Previous directions having been carried out, all that is required at present is to shut up the house, and, if frost occurs, do not let the night temperature fall below 40°, nor allow it to rise above 45°.

Early Vinery.—As the buds begin to swell, the night temperature may be raised to from 53° to 55°, with a corresponding rise in the day temperature. Spray the rods in the morning and early afternoon.

The Hardy Fruit Garden.

Nailing Wall Trees.—This work can be carried on in frosty weather; but while a touch of frost makes conditions quite comfortable, it is a shame to keep men at this operation under Arctic conditions. Nails will not rust if heated well and then dropped into linseed oil. In training young trees, leading shoots, if over-vigorous, should be bent downwards somewhat to check the flow of sap; while, on the other hand, weakly shoots should be inclined upwards to encourage the more rapid flow of sap.

Heading Back for Grafting.—Where grafting is contemplated on old Apple or Pear trees, they should be headed back with a saw, care being taken not to splinter the stock during the operation. Young stocks should also be headed back with a sharp knife to near the point where it is intended to operate. For dwarfs this should be about nine inches from the ground. In the case of standards, the height at which the stock should be cut depends upon the variety to be worked upon it. If a fairly vigorous variety, cut also at 9 inches from the ground, and form the rest of the stem with the scion.

The Vegetable Garden.

Repairing Box Edgings.—Any blanks in the Box edgings should be made up during fine weather. If there is no spare Box, a stretch should be relaid and the surplus used for "beating up."

Repairing Walks.—Now is the time to attend to this work. Happy are those who have access to good gravel without paying a ransom for it. If the vegetable garden does not occupy a very prominent position and is mostly regarded from the utilitarian point of view, rough ashes will form quite comfortable pathways at little or no cost. A walk when finished should be slightly convex in form.

CHARLES COMFORT.

Broomfield Gardens, Davidson's Mains, Midlothian.

THE SILVER-LEAF DISEASE OF FRUIT TREES.

ITS CAUSE AND PREVENTION.

(Continued from page 572.)

How the Silvering of Foliage is Caused.—

Although in the recognition of silver-leaf there is no difficulty, it should still be explained how the appearance comes about. It is primarily due, Mr. Brooks says, to the accumulation of air, either below the epidermal cells or in the cavities of their walls, the presence of air in these places interfering with the normal reflection of light from the surface of the leaf. The upper epidermis is more or less loose from the palisade cells. There is a marked tendency for the mesophyll cells to fall asunder when sections of the leaf are cut, and so pronounced is this that it is sometimes impossible to obtain sections of silvered leaves which will hold together.

Prevention and Remedy.—In the treatment of plantations it must be remembered that the cause of this disease, like many other fungi, is a wound parasite, *i.e.*, it attacks the tree only through its wounds. It is, therefore, correct to protect the wounds of a healthy tree by means of tar, and this ought not to be neglected. The sanitation of the district by destroying the *Stereum* itself, upon whatever it may grow, is highly important. Mr. Brooks says: "It cannot be too strongly urged that all tissues upon which the sporophores of this fungus appear in fruit plantations should be destroyed. Experiments indicate that *Stereum purpureum* taken from material such as a dead Birch stump is equally as effective in causing silver-leaf as *Stereum purpureum* taken from a Plum tree; hence no quarter should be extended to the fungus in fruit plantations, on whatever substratum it may be found." Experience has shown, Mr. Brooks says, that benefit is derived by cutting out affected branches. The recovery of slightly-infected trees is not infrequent, but no reason has been found to alter his suggestion that Plum trees badly silvered and beginning to die back should be destroyed. Grease-banding, improperly carried out, by application of grease to the bark itself, is believed to favour the development of silver-leaf disease. It causes death of the bark, and therefore provides a place for attack. Grease-banding should always be done by means of bands, so that the grease cannot penetrate to the bark.

Ferrous Sulphate as a Cure.—For the purpose of cure it has been suggested by fruit-growers in the case of Plum trees that ferrous sulphate should be applied to the roots; but this method of treatment was tried by Mr. Spencer Pickering on a considerable scale at the Woburn Experimental Fruit Farm a few years ago, without success. A similar method, by means of heavy dressings of ferrous sulphate with farmyard or artificial manure, has, apparently, been tried with success. The trees showed great improvement, and one became free from disease. Experiments after another manner have been observed by Mr. Brooks, that were carried out by Mr. E. Neaveon near Wisbech. Forty-nine silvered Victoria Plum trees about twenty years of age had a hole drilled in the trunk about three feet from the ground; about an ounce of ferrous sulphate was inserted in each hole, which afterwards was closed with a cork bung. This was done in 1910, and examination two years later showed that of all the trees 25 per cent. had recovered, while 34 per cent. of those only slightly affected had been restored to health. But these results, apparently, must be taken with caution,

for though ferrous sulphate is certainly poisonous to the mycelium or spawn, it is doubtful whether its influence would be extensive. Such a remedy, however, is worth trying, for certainly I remember having seen wood sections which had been coloured by the application of the salt of a metal dissolved in water, to the roots. Someone had conceived the idea of staining the wood in bulk while yet alive, and to a certain extent had succeeded, a blue colour being quite evident. The wood, I believe, was Beech.

Fungus Juice as a Remedy.—An interesting method of cure suggested by Miss Baker in the "Annals of Botany" for 1913 and quoted by Mr. Brooks, also by Professor Houston in THE GARDEN for May 3, page 215, must further be mentioned. It appears that a well-known and not uncommon fungus, *Coprinus comatus*, which may be found in meadows and gardens in the autumn, has the power of secreting a kind of digestive fluid by which it is itself digested. The fungus, by means of its digestive fluid, is rapidly deliquescent, and where it grew there presently remains nothing but a black fluid resembling ink. It is proposed, then, to use an aqueous extract of the fungus, both internally and externally, for the purpose of destroying the *Stereum* in the way that the *Coprinus* itself is destroyed. It has been tried on a Victoria Plum, and two years later the silvered branch became almost free from silver-leaf. The well-known phenomenon of auto or self digestion, shown by the fruit bodies of most species of *Coprinus*, forms the theoretical basis for this treatment, and it is even suggested that the separation of the cells of the leaf, to which the appearance of silver-leaf is due, may be brought about by an oxydase or enzyme which is secreted by the *Stereum*. This was suggested by Ferrival, and, I believe, is suggested by Miss Baker, but Mr. Brooks has not been able to confirm it. *Coprinus comatus* is easily recognised by its nearly cylindrical cap with peeling skin, which bears a fancied resemblance to a wig on a barber's block. It is edible, but is not so good as Mushroom. *Stereum purpureum* is a fungus of leathery consistence, projecting in scales, irregular in form, more or less umbonate and reflexed, tomentose or velvety and whitish or palid above, but zoned with darker marking; smooth, even and of pale clear purple below.

Warning and Conclusion.—In order that too much may not be understood or expected from what I have said about remedies, it cannot be too emphatically stated that no one has produced any reliable evidence of cure. Experiments tried with one or two trees are very far from conclusive, and should not be relied on. Numbers are necessary and "controls" essential. The trees, indeed, sometimes cure themselves, and the factor of self-cure in these cases is quite unknown. Mr. Brooks, in conversation, has kindly informed me that his extensive experiments in the use of ferrous sulphate have this year shown no good result, and this experience, it will be noticed above, agrees with that recorded by Mr. Spencer Pickering. In the case of Miss Baker's experiment, only one tree was tried, and I understand that evidence is not altogether promising. In this warning I desire to be emphatic, because I hear of a fine orchard of Plums now nearly destroyed which the owner might have saved by removing the first badly-infected trees. I have during the past summer visited Cornwall and Scilly, and have everywhere found the disease. It is, indeed, remarkable that although it must always have been extant, little

has been heard of it until recent years. For this, however, there are reasons. It has extended, no doubt, with the development of fruit culture, and formerly the loss of a tree would hardly have been remarked. A new tree would be planted and, being sound, it would be some years before it could be attacked. Experiments must continue; but with regard to the use of ferrous sulphate I should like to quote Griffiths' "A Treatise on Manures" (second edition, page 306). The author writes: "Iron sulphate in excess is a plant poison. It is well known that an excess of iron in a soil may cause a soil to become barren." The illustration on page 571 of November 15 issue represents *Stereum purpureum*, which I learn from Mr. Brooks is the only species that can cause the disease. An ally, *S. hirsutum*, yellow and not purple below, is therefore not to be feared. It is growing on the stem of an Apple Royal Snow, which had been cut down for grafting upon; hence the disease. This case certainly suggests precautions when grafting is done. In taking the photograph, size has been reduced to slightly less than one-half. For further information, especially of the convincing methods of Mr. Brooks' experiments, I must refer one to his papers in the "Journal of Agricultural Science," Vol. IV., Part 2, October, 1911, and Vol. V., Part 3, June, 1913, page 288, which has been recently published.

Botanic Garden, Cambridge. R IRWIN LYNCH.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" column. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

PLANTING SWEET WOODRUFF (C. M.).—The Sweet Woodruff (*Asperula odorata*) is by no means a fastidious subject, and may be planted at any time in open weather. The plant revels in light soils and does not object to heavier soils over chalk, but is less rampant on clay soils. If you secure established examples, there need be little fear of their not doing well; it is different, however, when only single-rooted shoots are planted. You do not say the purpose for which you intend the plants, but we would warn you not to plant on the rockery where choice plants abound. They are apt to get into every crevice and presently become a nuisance.

HERBACEOUS BORDER PLANTS (G. B.).—You cannot do better, we think, than arrange the border in groups. Starting at the front you might have *Aster sub-carolinensis*; alpine *Phloxes*, as *setacea*, *Vivid Nelsonii*, *atropurpurea*, *Model* and *amœna*; the newer *Mossy Saxifragas*, as *Gibranti*, *bathoniensis*, *sarzanica superba* and *Miss Willmott*; *Anemba echioides*, *Polygonum affine*, *Orobis verius*, *Adonis vernalis*, *Lycbuis Viscaria splendens plena*, *Lithospermum prostratum*, *Iris pinnula carulea*, *Delis sempervirens*, *Gentiana acutis*, *Aubrietias* and the like. These would look best if set among sandstone rocks in yard wide masses. Behind these another informal set of groups might be made up of *Impatiens glandulosa*, *Helianthus pinnifidus*, *Heuchera sanguinea* and its many varieties of hybrids, *Phlox canadensis*, *Gentiana Bradshaw*, *Potentilla Gibson's Scarlet*, *Aster Amelbis*, *A. River-lesha*, single and double *Pyrobrunus*, *Erigeron speciosus superbus*, *Delphinium Belladonna*, *Campanula persicifolia Albrechti*, *C. carpatica River-lesha*, *C. van Bontter*, *Aster acris*, *Aquilegia chrysantha*, *Thalictrum aquilegifolium* and *T. atrorubrum*; and in the back row herbaceous *Primes*, *Phloxes* white and scarlet, *Asters*

ricoides Deshe, Feltham Blue, Beauty of Colwall and cordifolius Ideal, Helianthus multiflorus, H. m. flore pleno, Iris pallida dalmatica and such Delphiniums as King of Delphiniums, Rev. E. Lascelles, Amos Perry, La France and Duchess of Connaught. These should have not less than three, and better if five, to each group or colony. The wider one might have a big flanking group of the white and pink Japanese Anemones stretching halfway across the border, and near to Aster Beauty of Colwall in like proportion. You would obtain many good hints about planting and grouping were you to consult "The Hardy Flower Book," by E. H. Jenkins, price 2s. 10d. post free from our Publishing Department. It is rich in lists and suggestions.

TREES AND SHRUBS.

PRUNING CEANOTHUS (A. R.).—Your Ceanothus Gloire de Versailles may be left unpruned until February, when you may cut the present year's shoots back about halfway. This pruning should be repeated annually, but if a number of very weak shoots are formed, some should be cut clean out and others pruned to within a bud or two of the base. There is no reason why you should not save seed of your Primula, providing you resort to hand pollination. Place the plant in the sunniest position you can.

THE GREENHOUSE.

CARNATION RUST (Leicester). The Carnation is badly attacked by the Carnation rust. The main thing to do is to keep the atmosphere dry and buoyant, and the temperature sufficiently high this does not mean avoid watering the plants. Pick off the affected foliage and burn it, and spray the plants with a rose red solution of potassium sulphide.

BEGONIA LEAVES TURNING BROWN (F. C., Suffolk).—The Begonias are badly attacked by the leaf-eelworm, *Aphelenchus olesistis*. This pest attacks many kinds of greenhouse plants, including Ferns, and usually dipping the plants in a wash containing nicotine is beneficial; spraying with the same might have a good effect. Fumigation is, in all probability, useless. The pest gains entrance into the plants through the stomata and comes from the soil. It is only when the plants are kept moist that the pest can travel to the stomatal openings. It would be well another year to discard the whole of the soil in which the plants are growing, and to clean the pots thoroughly before beginning to get a new stock. The stock must, of course, be a clean one, and it should be remembered that the dust on the potting-bench might be a source of infection.

FRUIT GARDEN.

PEACH TREE UNSATISFACTORY (C. C.).—The variety is subject to this complaint; but if certain cultural precautions are taken, among them those which you suggest, there is no reason why the difficulty should not be got over. Most Peach-growers make a mistake in keeping their trees too dry at the roots while the trees are dormant. Give your tree a good soaking of weak manure-water at once, and again at intervals of three weeks or so through the winter and spring. Keep your trees as cool as possible, with plenty of air on in favourable weather all through the winter. Fertilise the blossom at midday on fine days with the stronger pollen of other varieties in bloom at the same time. Give the tree a top-dressing of the following compost, 4 inches deep, after exposing the surface roots first: To one barrow-load of fibrous loam add half a gallon of bone-meal, the same of kail, a gallon of brick-ends, broken small, the same of old mortar rubble, also broken small, and a gallon of lime. Mix well together and tread firmly down when applied.

HOW TO PLANT A VINE (H. J. N.).—Any time next month will be a good time to plant your Vine. The size of your border should be 8 feet by 4 feet, by 3 feet deep. A border of this size will be large enough for the first three years, after which time 2 feet should be added to its width and length. For drainage you must lay down all over the bottom of the border a layer of broken brick-ends to the depth of 5 inches. A drain (3-inch) must also be laid down at the bottom side of the border for its whole length and carried out to an outlet, where a fall of at least 5 inches can be secured, for surplus water to pass away from the border (a slight fall must be given to the bottom of the border towards the drain). Place turves of fibrous loam, grass side downwards (with the grass out off), over the drainage close together and tread hard down. On the top of this fill the border with the following soil compost: To one barrow-load of turfy fibrous loam add a gallon of half-inch bones, one quart of bone-meal, one peck of brick-ends, broken small, the same quantity of old mortar rubble, also broken small, and one peck of lime. Mix well together before placing it in the border. In planting, turn the Vine out of its pot, shake away the soil from among its roots, cut off about an inch of the tip end of the roots, spread out the roots evenly about ten inches below the surface of the border, and cover over with soil, pressing it down firmly. Plant on a dry day, and the soil should be fairly dry at planting-time. Water the roots as soon as planting is finished, and then cover over the surface of the border with straw to the depth of 5 inches. Leave the straw in until the last week in March; then remove it and replace with a top-dressing of well-decayed manure, 4 inches deep. After planting, cut the young Vine back to within three buds of its base. Get a copy of "Fruit Growing for Beginners," price 1s. 3d. post free from our Publishing Department.

KITCHEN GARDEN.

INJURY TO CELERY (E. L. B.).—The Celery is attacked by the fungus *Septoria Petroselinii* Aui, and very badly. It is now too late to do much in the way of checking it, except to remove the affected foliage as completely as possible (no good can come from allowing it to remain). The disease is often carried in the seed, and we recommend the spraying of the young plants from early in June, or even in mid-May, onwards with Bordeaux mixture as a preventive measure.

MISCELLANEOUS.

CLIMBING ROSES TO GROW FREELY (F. W.).—Climbing Caroline Testout would be a good pink variety, and Reine Olga de Wurtemberg a good red.

VIOLETS AND RED SPIDER (Constant Reader).—The Violet leaves are badly attacked by red spider. The plants are probably rather dry at the root, and spraying with water, so long as the under side of the leaves is sprayed, will do much to rid the plants of the insects. Spraying with potassium sulphide, 1oz. to three gallons of water, is also a useful measure.

NAMES OF PLANTS.—Berkshire.—*Hemanthus Aurii*,—*Rushetts*.—1, *Abelia grandiflora*; 2, *Psoralea bituminosa*; 3, *Lactuca chondrilliflora*; 4, *Elichrysum serotinum*.—*P. C.*—1, *Chrysanthemum segetum*; 2, *Lychnis coronaria*; 3, *Tradescantia crassifolia*.—*M. W. G.*—1, *Centaurea Cineraria*; 2, *Spiraea Lindleyana*; 3, *Daelylis glomerata variegata* probably, but cannot tell without flowers.

NAMES OF FRUIT.—A. R. S.—10, 14 and 15, Blenheim Orange; 11, Tower of Glamis; 12, Round Winter Nonsuch; 13, Alfriston; 15, Sandringham; 17, Pearson's Plate; 18, Brandy Apple; 20, Wealthy; 21, Stamford Pippin; 22, Gloria Mundi.—*T. J. C.*—Bourré d'Anjou; season, November and December.—*Godwin*.—1, Norfolk Belling; 2, Wellington; 3, Ribston Pippin; 4, Bess Pool; 5, Ashmead's Kernel; 6 and 9, Annie Elizabeth; 7, Colonel Vaughan; 8, Bramley's Seedling.

SOCIETIES.

AUTUMN SHOW AT HERTFORD.

The twenty-second annual show of Chrysanthemums, autumn flowers, fruit and vegetables under the auspices of the Hertford Horticultural Society was held in the Corn Exchange and Market on November 5 and 6. The opening ceremony was performed by Lady Longmore. The society has established such a high standard of merit at its previous shows that it is very difficult to maintain it, and certainly more difficult to surpass; but it is gratifying to know that this year's show was well up to any of its predecessors in point of excellence. The silver cup given by Mr. R. W. Partridge of Hertingfordbury Park for the best group of Chrysanthemums was won by Mr. W. Stephenson, gardener to Mr. Ernest Pearson of Brickendonbury, and as he has now won the trophy three times, it becomes his own property. There were some very fine blooms in his group, the chief of which were Gilbert Drabble, Rose Bouquet, Mrs. R. Luxford, Mrs. R. C. Pullen, Evelyn Mason, Marjory Lloyd, W. Buckingham and Sylvia Skade. In the class for groups of miscellaneous plants there were only two competitors, although Mr. H. Smith, gardener to Mr. Brodie Henderson, generously stood down to give other exhibitors a chance, as he had won the first prize four years in succession. The first prize was taken by Mr. O. Catling, gardener to Mr. H. W. Clinton Baker of Bayfordbury, with a very tasteful arrangement of Cattleyas, Begonia Gloire de Lorraine, Bonvardias, Salvias, Crotons and Palms. Mr. W. Stephenson, gardener to Mr. Ernest Pearson of Brickendonbury, was second; but, though he had some good quality material, there was too much of it. The class for twenty-four cut Chrysanthemum blooms was a very strong one. Premier honours were taken by Mr. A. Haynes, gardener to Mrs. Browning of Braintree House, who has obtained first place in this class five times during the last seven years. His chief blooms were Miss A. E. Roope, a brilliant buttercup yellow (which secured him the prize for the best bloom in the show), F. S. Vallis, Hon. Mrs. Lopes, William Turner and Mrs. G. E. Whitty. The show was admirably managed by the members of the committee of the society, and the new secretary, Mr. W. Reynolds, is to be congratulated upon the ready manner in which he grasped his duties and performed them so ably.

LIVERPOOL HORTICULTURAL ASSOCIATION.

This association may be justly proud of the thirty-fourth autumn exhibition, for not only did it prove the most extensive, at any rate, of recent years, but the quality was distinctly above the average. The show was held in the well-lighted Corn Exchange on the 12th and 13th inst., and the entries were above the normal. The cut flowers still occupy the premier position in popular favour, as was clearly seen by the crowd that hovered round the principal class of thirty-six blooms, eighteen incurved and eighteen Japanese, in which last year's winner upheld his high position, and so secures the coveted silver challenge vase as his own personal property. Four entries were made and four prizes were awarded, as follows: Mr. C. Goves, gardener to Sir Gilbert Greenall, Bart.; Mr. G. Haigh, gardener to Sir W. H. Tate, Bart.; Mr. H. Osborne,

gardener to Thomas Woodsend, Esq.; and Mr. John George, gardener to Thomas Hinshaw, Esq. The first prize set was well in advance in size, but the honour of colour fell to the second prize lot. The principal flowers in the winning stand were: Incurved—G. F. Evans (which secured the National Chrysanthemum Society's certificate as the best bloom in this section of the show), Embleme Poitevine, Godfrey's Eclipse, Doris Rayner, Pautia Ralli, Mrs. P. Wiseman and others; Japanese—W. Turner (which was awarded the National Chrysanthemum Society's certificate as the best incurred in the exhibition), W. Mease, F. S. Vallis, Robert Pulling, President Viger, Mrs. G. Drabble, Mrs. A. E. Roope, Fred Green, Alice Lemon and Francis Jolliffe. Other classes of these two sections were well filled, the leading winners being, in addition to those already named, Mr. J. Young, gardener to W. E. Willuk, Esq.; Mr. J. Copple, gardener to H. Belk, Esq., who won three prizes; Mr. J. Williams, gardener to C. J. Procter, Esq.; and Miss Newsham.

Single Chrysanthemums found great favour, and undoubtedly would have held their own in any part of the country. The most prominent exhibitors were: Mr. P. Cauce, gardener to G. Nicholson, Esq., and Mr. L. Thomson, an enthusiastic amateur. The names of Mr. Cauce's half-dozen were Mrs. William Street, Miss Annie Street, Edith Pagam, Miss K. Wells, Ruby and Mrs. H. Herbert. These were fully 6 inches in diameter, and lovely in colour.

Turning to the plants, which to many are more delightful than the giants on the boards, for Liverpool growers are noted for their success in trained plants, Mr. W. Wilson, gardener to W. Cunningham, Esq., and Mr. T. Hitchman, gardener to Arthur Earle, Esq., are past-masters in this line. Miss Annie Shaw, a single-flowered variety, and William, both staged by Mr. Wilson, were wonderful creations. Mr. F. C. Keightley, gardener to Mrs. Duncan, is an excellent grower of the more natural grown or staked plants. In the miscellaneous plants, Mr. Hurd, gardener to L. G. Pilkington, Esq., and Mr. H. Osborne were to the fore in the aristocratic domain of Orchid culture, the latter staging a superb Cattleya Portia with eight spikes and thirty-seven blooms.

In the fruit section, Mr. T. Elsworth, gardener to W. E. Gladstone, Esq., had the finest collection, and Mr. J. Wright, gardener to E. Lord, Esq., excelled in four bunches of Grapes, while Mr. W. Wilson claimed two firsts for pairs of bunches, and Mr. W. H. Faulkner, gardener to A. P. Eccles, Esq., was first in one class. Messrs. John Lee, J. Bott, F. C. Keightley, J. Macfarlane and W. Mackerell divided the prizes in the Apple and Pear classes.

The trade exhibits deserve more than a passing notice; but space is the only excuse for this brief reference. Gold medals were awarded to Messrs. Stuart Low and Co., Messrs. Fishlock Brothers and Messrs. Mansell and Hatcher. The exhibits may be briefly summarised as follows: Messrs. Mansell and Hatcher, the Liverpool Orchid Company, J. Le Doux, Esq., and Messrs. Stuart Low and Co., Orchids; Messrs. Fishlock Brothers, floral designs; Messrs. Stuart Low and Co., Messrs. Young and Co., and Mr. C. A. Young, Carnations; Messrs. R. P. Ker and Son, Cyclamen; Messrs. W. Wells and Co., Messrs. Dicksons, Messrs. Chibans and Messrs. W. Rowlands and Co., Chrysanthemums; Mr. H. Middlehurst, vegetables; and Messrs. Thomas Davies and Co., winter-flowering Heaths. Mr. A. Calderbank received a certificate of merit for single Chrysanthemum Dr. Hodgson, and Messrs. Stuart Low and Co. for Carnation Gorgeous.

The committee deserve every credit for their efforts to please both the exhibitor and visitor.

BOURNEMOUTH GARDENERS' ASSOCIATION.

ON Tuesday, November 18, a very able and interesting lecture was given by Mr. G. H. Heath of Glenallock Gardens on "Zonal Pelargoniums for Summer and Winter Flowering." Mr. Heath grows these plants remarkably well, and has won the principal prize for them in the classes at the Bournemouth shows for eight years consecutively in very keen competition. He recommends cultivators to propagate cuttings for summer flowering in July and for winter flowering in August. As a general compost he advises leaf-soil one part, turfy loam three parts, with a small quantity of bone-meal and a sprinkling of old lime. Firm potting was essential to success. When grown for exhibition, the plants should be topped soon after they were first potted, and again when finally potted. A small quantity of sulphate of ammonia intensified the colour of the flowers. Nitrogen caused the leaves to grow very large, but did not induce flowers to form. He relied on potash and phosphates. Many questions were asked and ably answered, the discussion being free and instructive.

In the "Points" Competition Mr. Heath had three fine vases of single-flowered Zonals, namely, Phyllis, Princess of Wales and Sir F. Danbury. Mr. Smith, gardener to the Dowager Lady de Tabley, staged Cypripediums; and Mr. Pearce, gardener to Mrs. Ormoud, Crotons, Ferns, and a fine Pandanus Veitchii. Messrs. George Bunyard and Co., Limited, Mail-stone, sent twenty-four dishes of beautiful Apples. The following were the varieties: Lane's Prince Albert, Bramley's Seedling, Gascoyne's Scarlet Seedling, Handbills' Seedling, Newton Wonder, Norfolk Beauty, Lord Derby, Blenheim Orange, Allington Pippin, King of the Pippins, Mere du Menage, Sanspareil, Cox's Orange Pippin, Mother Bismarck, King Edward VII., Tower of Glamis, Waltham Abbey Seedling, Peasgood's Nonsuch, Baumgarten's Red Kenette, Alfriston, Royal Jubilee, King of Tompkins' County, and Stirling Castle. At the close of the lecture the Apples were sold to the members, the money being given to the Royal Gardeners' Orphan Fund. Messrs. Bunyard, the lecturer, and Mr. Garner, who presided, were accorded hearty votes of thanks.

EDITORIAL NOTICES.

Every department of horticulture is represented in **THE GARDEN**, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles, and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavor to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographs, or copies of the copyright will be treated with

*The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in **THE GARDEN** will alone be considered as acceptance.*

NOTES OF THE WEEK.

Official Guide at Kew.—As we mentioned some time ago, an official guide to conduct parties of visitors round the famous gardens at Kew was appointed. The charges for the services rendered by the guide have now been reduced from 2s. 6d. to 6d. each person in the morning, and from 1s. to 3d. during the afternoon. Full particulars concerning the guide can be obtained on application to the Director, Royal Gardens, Kew.

The Flagstaff at Kew.—The wood of the Douglas spruce has decayed so much during the last few years that it has been found necessary to take it down for repairs. This was safely accomplished on Monday, November 24. The flagstaff, which is a splendid example of the Douglas Fir, *Pseudotsuga Douglasii*, was presented to the gardens by Mr. Edward Stamp in 1861. It was obtained from British Columbia. The pole is 150 feet high and 20 inches in diameter.

Banding Laburnums.—Laburnums have a habit of splitting at the lowest fork in the tree. Where signs of this are seen, the tree should have an iron band placed round it just below the fork. The two ends of the band should be turned back to a right angle, each projecting end having a hole pierced through it, one of which should be square. Through these a bolt with a square shoulder and fitted with a thread and nut should be thrust, and the nut should then be screwed up till the band clasps the trunk firmly. Give the band two coats of olive green paint.

Pruning Gooseberry and Currant Bushes.—In many parts of the country bullfinches and tits are very destructive to the buds of Gooseberries and Red and White Currants, during the winter and early spring. If, after the pruning is done, the bushes are given a good syringing of petroleum emulsion to make the buds distasteful, the work may be done now with safety and thus save time in the spring.

Pruning Large Trees.—When cutting or pruning is required among large trees, the work should not be delayed, for it may be noticed that the sap of many of them, particularly those with large leaves, such as Horse Chestnut, Walnuts and Sycamores, commences to flow early in the New Year. Any cutting that is required to members of the conifer family should also be done now, and not left till the spring.

Wart Disease of Potatoes in Ayrshire.—The Board of Agriculture and Fisheries desire to inform all Potato growers and dealers that in consequence of an outbreak of wart disease in Potatoes in North Ayrshire they have passed an Order prohibiting the introduction of Potatoes from that district into England and Wales. All persons who have already received seed Potatoes from that district should carefully examine the tubers, and if any

sign of disease is apparent, the Board should be informed. Dealers and growers are reminded that it is illegal to plant or sell for planting any Potatoes attacked by this disease, under a penalty of ten pounds.

Rose Hedges.—These are suitable for almost any part of the garden where a hedge or screen is wanted, but they are specially adapted for enclosing or dividing the Rose garden. At least four classes of Roses are suitable for this purpose, viz., Chinas, Austrian Briars, rugosas and Penzance Briars. For a dwarf hedge the Chinas, especially the Old Blush or Monthly Rose, Mme. Bosanquet, Lellenberg and Laurette Messimy, are suitable. For hedges of moderate height the Austrian Copper and Austrian Yellow are good; while the varieties of Rosa rugosa and of the Penzance Briar will be found the most suitable for taller hedges. In addition to their flowers, the rugosas and the Briars have their decorative value enhanced by their bright red hips.

The Winter Jessamine.—The mild weather this year has been very favourable for the development of the flowers on this delightful climber. Flowering in midwinter, the blooms are liable to damage by frost, yet Jasminum nudicaule is worth a place in every garden, on a fence or wall, where it is able to make such a pleasing display with its thousands of bright yellow blossoms, as is the case this year. The aspect of the fence or wall against which the Winter Jessamine is planted appears to make no difference to the free-flowing qualities of the plant. The specimen which suggested this note is on a west wall. The sprays are delightful to cut for indoor decoration, being particularly effective arranged with sprays of Ivy in small vases on the dining-room table.

A Good Ash Tree for the Lawn.—Fraxinus Mariesii is a very suitable tree for planting as a lawn specimen, for it is of considerable decorative merit and rare. It belongs to the group of the genus which is characterised by showy flowers, and is closely related to the Mamia Ash, *F. Ornus*, a European species which is fairly common in the British Isles. *F. Mariesii* is a native of China, and was discovered by Mires in the Lushan Mountains near Kiukiang. He sent seeds to Messrs. Veitch in 1870, and the first plant flowered in the Coombe Wood Nursery in 1882. It grows into a small, round-headed tree with purplish branchlets. The pinnate leaves are made up of five oval, acuminate or acute leaflets, which are up to 3 inches in length, but show some considerable variation in size. The creamy white flowers appear in large, upright panicles during June or early July, and are succeeded by the familiar winged seeds peculiar to the Ash. In this case they are purplish in colour. Like other Ashes, it succeeds best in good, loamy soil of a moist, yet well-drained character. Growth is rather slow, and for that reason it is well fitted for positions where space is somewhat restricted.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Pears Flowering at the End of November.—

At the present time there are three Pear trees variety, *Beurré de Amandis* in full blossom here, which shows the wonderfully mild autumn we have experienced. I enclose a photograph of one of the trees, also a branch of the blossom—**D. WAIT, Vice-regal Lodge Gardens, Dublin.** [Unfortunately, the photograph was not quite sharp enough for reproduction.—ED.]

Perennial Aster Perle Rose.—In general appearance this variety resembles the blue Italian Starwort (*Aster Amellus bessarabicus*), but the flowers are of a beautiful rosy pink colour. It is unquestionably a worthy subject for the rock garden in autumn, although it appears to be very little known, for I have looked in vain for a mention of it in numerous catalogues. The illustration depicts this variety as seen in October last in a shady corner of the rock garden at Copped Hall, Epping. Here it is used with good effect under the shade of trees and in association with hardy Ferns, where few other flowering plants could be expected to thrive.—**C. Q.**

Gentiana verna.—Mr. Malby's note, page 548, issue November 1, was of particular interest to me, for the value of glass covering for *Gentiana verna* was proved here last winter, a much better display of flowers being produced on protected plants than on those left unprotected. Mr. Arnott's method of "mulching" with small stones or similar material has been found of great advantage, especially in cold and low-lying districts. Such treatment, given to several of the weaker alpinas here, has produced good results. For myself I feel sure that, provided with a fairly porous compost, a sunny position and protection from winter rains, *G. verna* will give but little more trouble than its more robust companion *G. acialis*. In addition to *G. verna*, we make it a rule to protect several of the choicer alpinas which are at all weakly by a glass covering, and in all cases it has proved beneficial. **H. TURNER, Selby Gardens, York.**

Cordyline australis.—Referring to a note on page 570 of your issue of THE GARDEN for November 15 on the above Club Palm, it may interest "T. C. F. M." to know that this plant succeeds remarkably well in the open garden in the South-West of Scotland; in fact, we look upon this as the hardiest of the many tender plants growing in the open here. There are plants in all sizes, from a two year old seedling to the parent plant over twenty feet high. The older plants receive no protection during the winter, and on various occasions they have been exposed to 18° and 20° of frost (ground temperature), but I have never

known even a young plant to be killed. The soil here is a deep black loam, with good drainage, which seems to suit them very well. Young plants from 3 feet to 8 feet will put on 2 feet of growth in a season. They also seem well adapted to plant in a windy situation; at least, we have never had one blown over in this wind-swept district.—**GALAWA**

Dahlias at Chrysanthemum Shows.—After twenty-five years' experience serving on councils and committees of horticultural societies, I quite realise the difficulties that beset many such councils in providing classes that will be an additional attraction to cultivators and the public. Orchids, Carnations, Zonal Pelargoniums and winter-flowering Begonias find a place in the schedules of the majority of shows, in addition, of course,

Perseus shows. Perhaps some of our expert growers will give their opinion.—**GEORGE GARNER.**

Disbudded v. Undisbudded Roses.—What a difference there is in blooms of nearly all Roses that are the result of disbudding directly the buds are large enough to handle, compared with the flowers of the same variety from plants that are allowed to develop all their buds into blooms in clusters. Flowers from the latter method are often not discernible as being typical of certain sorts. For instance, note the difference in blooms of Edward Mawley, Mrs. Cornwallis-West, Mrs. E. Powell, or Gloire de Chedane Guimoisseau. In size of petal, richness of colour, or general form there is no comparison. For purely garden decoration the undisbudded plants may be interesting as giving a mass of flower, but where Roses are prized for cutting and the individual merits of the different varieties are to be maintained, then disbudding is an advantage. I do not mean to reduce the number of shoots upon a plant to obtain one or two huge blooms for exhibition, but I prefer to allow all shoots to grow and confine the buds to one on each shoot. By this method stouter, stiff shoots are obtained, with a representative bloom of each variety well supported with foliage, which for vase decoration plays an important part, as no other foliage tends to show off Rose blooms so well as their own.—**E. M.**

Culinary and Dessert Apples for Suburban Gardens.—

In choosing varieties of Apples, or, indeed, any other fruits, one of the chief objects should be to secure those varieties which will prolong the season. In large gardens this is usually so ordered, though now and again one comes across an establishment where the successional arrangement might with advantage be improved upon. But I write for the smaller garden, of one to three acres, say, of which there are an ever-increasing number springing up on the outskirts of this and every other city. The methods of preparing the positions and planting the trees are so frequently touched upon by authoritative writers that I pass on at once to enumerate a few reliable sorts for the twofold purposes, culinary and dessert. Early Victoria, Potts' Seedling, Stirling Castle, Warner's King and Bramley's Seedling will carry the kitchen supply in the order given to Christmas, after which Beauty of Kent and Lane's Prince Albert would make provision until the end of March—certainly a very satisfactory period for such an acreage of ground. For a supply of dessert or table fruits extending over a similar period, we have found the following highly serviceable: Beauty of Bath or Irish Peach, James Grieve, Cox's Orange Pippin, and Lord Hindlip or King's Ace Pippin. It will be found much more advantageous to grow several trees of a limited number of varieties than a host of sorts all ripening one upon the other.—**C. TURNER, Ken View Garden, Highgate, N.**

ASTER ROSE PERLE IN THE GARDENS AT COPPED HALL, EPPING.

to the Chrysanthemums, fruits and vegetables. The last week in October and the first week in November is rather late in the season for staging Dahlias, but there have been thousands of fine flowers as late this autumn, and I feel sure that if classes are provided for these flowers in future years, the latter will be seen well staged. Cultivators will find a means of protecting their blooms in adverse weather. To begin with, societies might provide an open class for a display of Dahlias in a given space; other open classes may be listed for the Cactus, single and Pompan sections. The local classes must also be remembered. I think the inclusion of Dahlias would prove a great attraction and win a lot of extra support for our many Chrysanthemum shows.

Warner's King and Bramley's Seedling will carry the kitchen supply in the order given to Christmas, after which Beauty of Kent and Lane's Prince Albert would make provision until the end of March—certainly a very satisfactory period for such an acreage of ground. For a supply of dessert or table fruits extending over a similar period, we have found the following highly serviceable: Beauty of Bath or Irish Peach, James Grieve, Cox's Orange Pippin, and Lord Hindlip or King's Ace Pippin. It will be found much more advantageous to grow several trees of a limited number of varieties than a host of sorts all ripening one upon the other.—**C. TURNER, Ken View Garden, Highgate, N.**

Rose Mme. Abel Chatenay.—For several years I have had a very strong liking for this Rose. As a town garden variety it is a great success. It possesses so many good points. In my garden it has continued to flower since last June, and now bears clean buds. While some Roses near it are milled, this one is free. The colour is so very pleasing and effective when the blooms are arranged in baskets or vases. Quite small buds, if cut and placed in water in vases in the dwelling-house, open fully, retain their colour and remain fresh for nearly a week. All who grow this variety appreciate its many good points. Those who do not possess any plants should add several to their collection this autumn.—Avon.

Early Peas in Pots and Boxes.—A sowing of early Peas made now in turf and placed on a shelf near the glass will be just right for potting up in the New Year in the Chrysanthemum pots. Suitable varieties are numerous, but we find that Sutton's Excelsior and World's Record surpass anything in Peas we have ever tried. Both finish with full pods. The former is dwarf and the latter medium in height, and both suit various houses. World's Record is also suitable for borders and raised beds. Our soil being very heavy, we pass it through a coarse sieve, mix some approved fertiliser with it, crock the pots in the usual way, and three parts fill them with the soil and firm down. Place the turf and Peas on this, stake them with a short stick, and place them in a cool house near the glass. As the days lengthen they will grow faster, and need a house to themselves if a quantity is required. Repeat the sowing every fourteen days for a continual supply. Continue potting as above. Both the sowings and pots have given as good results as those grown outside, and the seeds germinated without a break in a house 30 yards long.—T. G. J., *Shaftesbury, Dorset.*

The Rock Garden in Autumn and Winter.—At all times of the year the rock garden can be made to possess some charm and interest, although I must admit that in late summer, autumn and winter the beauty is somewhat limited as far as flowering plants are concerned. Nevertheless, much can be done to increase the attractiveness at that time, when flowers are not so plentiful, by the more liberal use of many of those plants with ornamental foliage. The beautiful silvery appearance of many of the Achilleas, Ageratums, Artemisias and similar plants, with the beautiful tints obtained from many of the Sedums and Sempervivums, which these plants give us from late summer onwards, from beautiful crimson, pink, yellow, and many shades of greens, all blend in harmony with their surroundings, whatever they may be. Yellow is perhaps a limited colour in foliage, although there are a few yellow-foliaged varieties of plants, such as the golden *Sagina*, the yellow variegated *Arabis*, the golden variety of *Sedum acre* and a few others, which are worthy of a place. By using such plants more freely than is generally the case for the value of their foliage, we may greatly assist to link together with touches of beauty one season of flower to another.—F. PRESTON.

FORTHCOMING EVENTS.

December 8.—United Horticultural Provident and Benefit Society's Committee Meeting.

December 10.—East Anglian Horticultural Club's Meeting. North of England Horticultural Society's Meeting and Lecture at Leeds. National Chrysanthemum Society's Exhibition at Essex Hall, Strand. Conference in the evening

GARDENING ACROSTICS.

AS announced in our issue for last week, we are publishing eight gardening acrostics, to be divided into two sets of four each. Each light correctly guessed will count one, and also each "first" and each "last." Thus, supposing the whole is China (firsts), Aster (lasts), the full marks will be seven—one for China, one for Aster, and one for each of the two lights C . . . A, H . . . S, I . . . T, N . . . E and A . . . R. Hence, suppose a competitor got everything right but the light I . . . T, he would count six, and it would not matter if he attempted to solve that particular light or not.

Those entering for the acrostics must observe the following conditions:

- (1) Solutions must be addressed to The Editor at 20, Tavistock Street, Covent Garden, W.C., and bear the word "Acrostic" in the top left-hand corner of the envelope.
- (2) If a *nom de plume* is used, competitors must at the same time enclose their own name and address, not, of course, for publication.

MR. F. JENNINGS, THE HEAD-GARDENER AT CHATSWORTH. (See page 610.)

- (3) Solutions must reach the Editor within a week of the date of issue in which the acrostic appears. Thus, solutions of Acrostic No. 1 published in THE GARDEN to-day must arrive at the office before or by the first post on December 13.
- (4) A list of those who have sent in solutions, with the number of marks that each one has obtained, will be published in the next issue. Thus, that of those who compete in Acrostic No. 1 will appear in the issue dated December 20.
- (5) We propose to divide the series of eight into two or four each, and to award two prizes at the end of the fourth, and two more at the end of the eighth and last. The first prize in each case will be two guineas, or books of that value, and the second, one guinea. In order to give as many as possible a chance of a prize, the winner or winners of the first prize in the first four will be penalised twelve points, and, similarly, the winner or winners of the second, eight points if they enter for the second four.

- (6) In case of any dispute, the Editor's decision must be accepted as final.
- (7) No solution can be accepted as correct unless it is the one that the framer of the acrostic has sent us as his solution, and which we shall publish in due course. It is impossible for it to be otherwise, as it would lead to much confusion, and it would place upon us a responsibility which we could not assume.
- (8) In the event of two or more competitors obtaining an equal number of marks for first prize, the first and second prizes will be added together and divided among them.

DOUBLE ACROSTIC No. 1.

- Firsts—A Vine.
Lasts—A most useful part of my "firsts."
- 1. 60 "3 inch."
 - 2. A vegetable—purple when eaten in ancient Rome; green or blanched when consumed in modern London.
 - 3. An almost hardy bulb with a flower not unlike what a blue *Freesia* might be.
 - 4. The author of a beautiful gardening book. "Nothing approaches it for instructiveness in herbaceous plants till we get to Robinson's 'English Flower Garden.'"
 - 5. Our greatest and oldest living botanist.
 - 6. A Georgian Tulip. One of the best doers of all the large-flowered, brilliant-hued species.
 - 7. A dainty pea of Tussac's day.

Solutions of the above must be sent so as to reach the Editor at 20, Tavistock Street, Covent Garden, London, W.C., not later than the first post on Saturday, December 13. Mark the envelope "Acrostic" in the top left-hand corner.

ROCK AND WATER GARDEN.

THE DESIGNING, CONSTRUCTION AND PLANTING OF ROCK GARDENS.

(Continued from page 596.)

ATHIRD site that one is sometimes called on to consider is a dry hollow in a hill-side. Earth, gravel or other material has been removed for use elsewhere, and left more or less abrupt banks; it is a veritable sun-trap, and sheltered withal. The introduction of water may, or may not, be out of the question, and if it is introduced will somewhat effect a modification in the design. Here we will consider it without water, as it may be convenient at a later stage to point out how the scheme should be altered to admit of its use. This is a spot where the sun-loving alpine will revel, while, by judicious arrangement, sufficient shady positions can be introduced to permit of the successful culture of many of those that prefer cooler conditions. The best method of dealing with this site will be, I think, to treat it as a natural cliff formation, from which broken boulders and crumbling fragments have become detached and fallen in all directions. I have already described the processes by which in Nature the crevices between these fallen masses become filled with particles of earth that are washed down from above, and by the growth and decay of the lower vegetable forms, thus rendering them suitable receptacles for the culture of alpine plants, which, indeed, find their natural homes prepared by the same processes. Paths and steps will be required, but should be as rudimentary as is consistent with comfortable

SKETCH F, SHOWING SECTIONAL TREATMENT OF SITE.

transit; in some cases they may be barely possible, although every foothold should be made absolutely secure. Sketch F shows in section the treatment of this site.

If time and space permitted, I could go on multiplying descriptions of varying sites; but there must be an end to all things, and I think I have said enough to illustrate the fact that every position demands separate consideration, and, generally speaking, possesses in itself a potential design all its own. There are, however, certain sites much more suitable than others, and some, indeed, that should be avoided. If the intention (and I want to lay particular stress on this distinction) be purely for the cultivation of a collection of alpine, then the question of design hardly enters into the matter. If the rock is to be used primarily for the production of picturesque effects, then it should be used in positions that offer some natural advantages and are removed somewhat from the more formal portions of the garden.

There are some people who seem to think that a successful rock garden can be made in the corner formed by two walls in the kitchen garden; others, that an admirably suitable place is under trees "where nothing else will grow, you know"; and yet others who imagine that by making a little hole in an odd corner, filling it with water and surrounding it with fragments of stone selected from the *débris* of some decayed building, they are creating a rock garden. Broadly speaking, the most favourable positions are light, airy, open spots on sloping ground. The only trees permissible are such as *Abies*, *Fines*, and others that associate naturally with bold masses of rock, and these only when the contour is rugged and weather-beaten in appearance and when they are some distance removed from the central positions in which it is desired to cultivate alpine plants. Silver Birches are permissible, and, where the work is bold and free enough in character, even desirable; but they must be in such positions that they will not overshadow the other inhabitants or send their fibrous roots to rob their weaker associates of sustenance.

Next week I hope to deal with the selection and arrangement of the stone, two items that are of considerable importance in the construction of rock gardens.

Colchester.

GEORGE DILLISTONE.

(To be continued.)

FLOWER GARDEN.

THE NAMING OF TULIPS.

HOW curious some of our old lovers and growers of the Tulip of fifty years ago would be could they read of a place where growers had breaks "in some varieties amounting to 30 per cent.," as Mr G. W. Leak reports of his collection at Wisbech on page 574 of November 15 issue. In those times, of course, Tulip lovers desired the rectified or final stage of the Tulip; the self or breeder stage was merely of value in the promise that it gave of some future break, of a fine feathered bloom or a noble flamed flower. Now, the desire would seem to be, in the case of the Darwin, to keep to the present beautiful self shade. As to how

to keep them in the self stage or how to cause them to break, no one knows. When growers were very plentiful, say, fifty years ago down to twenty-five years ago, all sorts of experiments were made in the direction of getting Tulips to break, with little success. Some men could break Tulips; others could not. Again, in some years very few would break; as Mr Leak says, such a small percentage as two per thousand. Another season almost all of one variety might break. Last year I had about a dozen bulbs of a treasured breeder or self, Beauty of Litchurch, lovely light lilac, and from which I was trying to work up a stock. At blooming, however, every one of them broke very badly, though I had not had a break in the previous fifteen years.

It must not be forgotten that all Tulips will break, or, perhaps, I had better say, are liable to break, sooner or later. The self or breeder condition of the bloom is simply a *stage*; the rectification will follow. We shall have good breaks and bad breaks—some "only fit to be thrown on the dustheap," as Mr. Leak says, others worthy of admiration. Again, it is quite likely there will be two kinds of breaks, but time will show whether there is any need to distinguish between them, just as in the case of our florist varieties some break in a feathered state, some in a flamed state, others in such a muddled way and so indistinct as to be considered worthless and, consequently, are discarded. In like manner other types of Tulip varieties break.

However a Tulip breaks, it should still be called by the same name, presuming that it has already been named in the self state. Clara Butt is always Clara Butt, whether in the self state or in the

rectified condition. It is still Clara Butt, whether it is wearing its morning or its evening gown. Again, in the rectified state you may have Krelage's break or Leak's break. It is quite possible that we may have two kinds of breaks. It will doubtless be within the capability of the Tulip Society to distinguish between them.

Reverting to the remarks made by Mr. Jacob in your issue of October 25; in the case of Sir Joseph Paxton we had Mellor's break, Lea's strain and Barlow's strain, and one also heard of the Wakefield Paxton. All these mean that Mellor had broken a first-rate Paxton, that Lea had a first-rate Flamed Paxton, and that Barlow had a celebrated Premier Flamed Paxton. Mellor was residing in Wakefield; hence the term "Wakefield Paxton." Probably very little lies in the distinction, each man doubtless proclaiming the excellence of his strain. After a few years all these questions of strains quietened down, and Sir Joseph Paxton would be described by just the stage it happened to be shown in or, as one may say, by the dress it was wearing at the time, self or breeder, feathered or flamed. I have "broken" Paxtons myself in recent years equal to any of the "strains" of the earlier growers. Though I have said Tulips will rectify or change, it is also true they are not constant in their markings,

A DISEASED DAFFODIL BULB. (See text)

and in this department lies the principal charm of Tulip culture. What we describe as Clara Butt is a Tulip of a certain shape, a certain form, quite distinct, and capable of being described and distinguished from every other Tulip. The mere fact that to-day it is in a self state, and that next year's bulb throws a bloom that is rectified, striped or flamed, does not justify us in saying the rectified type is a different variety; it is merely a different condition of the same variety.

It is a practice of the Tulip Society not even to allow two sister seedlings to be called by different names unless they can be brought on the table before the judges and shown to be distinct. The difference must not be accidental phases of growth, such as one seedling being rather dwarfed and another very tall; the blooms themselves must be so distinguishable from each other that one would say they were distinct. Why, then, should it be desirable to have one variety called by different names because in one case we have a self, in another case we have the same thing rectified, a very desirable break, a very worthy bloom, and in another case the same variety broken badly and "worthy of the dustheap"? A careful grower discards freely it need be, and by the process of selection obtains the best strains which go to make up a good collection. The Royal National Tulip Society are to co-operate with the Royal Horticultural Society in their endeavour to correct Tulip names when blooming-time comes.

Hale, Cheshire.

CHARLES W. NEEDHAM

A DISEASE OF NARCISSUS BULBS.

The following article by Mr. George Massee, F.L.S., is reprinted from the *Kew Bulletin*, No. 8, 1913, by special permission of the Controller of His Majesty's Stationery Office. These Bulletins, which are published at frequent intervals, are useful to those interested in gardening, and can be obtained through any bookseller from Messrs. Wynman and Sons, Fetter Lane, E.C., or direct from His Majesty's Stationery Office, Westminster, price 4d.

About three years ago a disease of an unusual nature was met with on various kinds of Narcissus bulbs. During the present season the disease has increased to such a serious extent that, according to the statement of growers on a large scale, entire plots of bulbs have been completely destroyed. The injury is due to the presence of a parasitic fungus called *Fusarium bulbigenum*, Cooke and Mass., first described in 1887, the host being given as a Narcissus bulb. At that time it was not recognised as a parasite.

As a rule the presence of the parasite is first indicated by the appearance of small, yellowish spots on the leaves. These spots gradually increase in size, become brown and dry, and become more or less covered with pale salmon-coloured specks, which are at first more or less gelatinous, but soon become dry and horny when exposed to the air. These coloured patches are masses of *Fusarium* spores, which are dispersed by various means and infect neighbouring plants. The mycelium present in the leaf can be traced passing downwards into the bulb, where it grows vigorously and spreads rapidly in the fleshy bulb-scales. During the early stage of infection of the bulb, the tips of the scales only are injured, as indicated by the brown colour. The injury, however, gradually extends to the base and enters the "cushion," whence it spreads rapidly, and very soon the entire bulb is of a uniform brown colour. When this stage is reached, the fungus forms delicate, whitish sheets

between the bulb-scales, and numerous chlamydospores or resting-spores are produced on the mycelium present in the substance of the scales. These spores are globose, colourless, with a thick cell-wall, and are produced at the tips of branches, or occur in chains in the length of the mycelium. They vary from 10-14µ in diameter. The *Fusarium* spores are borne in clusters at the tips of short branches, and in the mass are tinged salmon colour, but are colourless under the microscope. They are three-septate, tips pointed and slightly curved. In size they vary from 10-50 x 5-6µ.

When a bulb becomes brown, it soon commences to decay, and its complete destruction is hastened by the attacks of various kinds of saprophytic fungi, *Penicillium*, &c., and by saprophytic col-worms, such as species of *Rhabditis*. When bulbs decay in this manner before lifting, as frequently happens, the soil becomes infected by the liberation of the chlamydospores, which infect future crops. The germinating chlamydospores emit one or two short, slender branches, which bear a few short chains of minute, colourless, elliptical secondary spores, measuring about 3 x 2µ. These minute spores are the first to infect Narcissus leaves in the spring, after which the disease is continued throughout the season by means of the *Fusarium* form of spore.

The young leaves of a Narcissus about an inch long were infected with *Fusarium* spores, and in six days yellowish spots appeared at the points of infection, and as the leaves continued to increase in length, other diseased spots appeared lower down the leaf, mycelium in all instances being present in abundance in the tissues a week after the infection period. It is highly probable that the first infection, by means of the minute secondary-spores produced by the chlamydospores, occurs when the leaves are quite young, and that the disease gradually descends to the base of the leaf and into the bulb by a series of subsequent infections lower and lower down the leaf, due to independent infections by spores washed from diseased patches higher up the leaf. Chlamydospores are present in abundance in the tissues of the leaves.

The continuance of this disease may be due to two independent causes:

1. Slightly-diseased bulbs, containing the *Fusarium* spores or chlamydospores. Such bulbs are not readily detected when the injury is slight; however, when cut in two the presence of disease is readily indicated by the browning of the scales near the neck of the bulb. It is very doubtful whether soaking slightly-diseased bulbs in a fungicide would kill the mycelium present. It certainly would not kill thick-walled chlamydospores or resting-spores.

2. Infected soil. Whenever a crop of diseased bulbs has occurred, it may be concluded with certainty that the soil is infected, due to the decay of bulbs before lifting, and to fallen diseased leaves, both of which contain chlamydospores in their tissues. So far as is known at present, the fungus has only been met with on Narcissus bulbs, but most probably in course of time it will extend its ravages to other bulbous plants. Under the circumstances, the safest course would be to avoid planting bulbs for two or three years on land that had produced a diseased crop. No kind of dressing would be likely to destroy the chlamydospores directly, but during the spring, when they are germinating and producing secondary-spores, the latter would be killed by a dressing of kamit, or of sulphate of potash, lightly worked into the soil.

The disease is known in Holland, from where, quite unintentionally, the disease may often be

reintroduced into this country by means of slightly-infected bulbs.

Description of the Figures. 1. Section of Narcissus bulb, showing early stage of disease. Natural size. 2. Branched mycelium bearing clusters of *Fusarium* spores, x 400. 3. Chlamydospores or resting-spores, x 400. 4. Chlamydospores germinating and producing secondary spores, x 400."

THE FRUIT GARDEN.

HINTS ON PLANTING PEACHES AND NECTARINES.

THERE are many warm positions on walls in gardens where Peaches and Nectarines will thrive and be fruitful if properly planted and judiciously managed afterwards. The proper management of these trees does not involve a great deal more labour than is necessary in the case of Pears, for instance, and they are well worth the extra trouble.

Planting.—Trees with very strong young shoots are not the best to plant, for if planted in a deep, loose, rich soil, they may not bear fruits for several years. I know of a case in point where the trees did not bear for seven years after being planted, notwithstanding all efforts to induce them to do so by lifting, root-pruning and the withholding of manure. Those young trees possessing rather small twigs which are wiry and short-jointed and well studded with flower-buds are the right ones to plant. They are, really, in a fruit-bearing state, and should be retained in it. To this end they must be planted in a very firm rooting medium. The soil should be broken up to a depth of 30 inches. No manure must be put in, and it should be made very firm again prior to the planting of the trees. There is no better time for dealing with the soil than while it is in a really dry condition. It can then be firmed, and when the roots are covered the finer soil can be well placed around the smaller roots. Rather than plant in a rich, loose soil, I would place the roots on the surface of unbroken soil and earth them over, as the trees would make more satisfactory growth afterwards. South, south-east and south-west aspects are the best for Peaches and Nectarines. The south and south-west are the best two to select. Keep the roots near the surface covered with 3 inches or 4 inches of soil, and the main stem 9 inches from the wall. Any very strong, straight tap-roots may be cut off; but small ones should be bent forward and a large slate placed under the whole of the roots, as this will prevent them growing directly downwards at first.

Varieties to Grow.—Hale's Early, Royal George, Alexander, Crimson Galande, Dymond and Noblesse. For growing on walls in the open air select Hale's Early, Crimson Galande and Royal George. The latter is subject to mildew in some seasons, but if protected from cold winds in the early stages of growth, mildew will not be troublesome, and the variety is such a grand one that all amateur fruit-growers should possess it. Of Nectarines grow the following: Elruge, Early Rivers, Humboldt, Pineapple, Violette Hâtive and Balgowan. For outside walls plant the latter, Violette Hâtive and Elruge. Immediately the trees are planted, put on a surface mulch of half-rotted manure. Leave all tying up to be done in the spring; then the roots can settle firmly in the soil.

G. G.

GARDENS OF TO-DAY.

CHATSWORTH.

CHATSWORTH, the Derbyshire seat of His Grace the Duke of Devonshire, which the King and Queen are next week honouring with their presence, has, on more than one occasion, not inappropriately been termed the Palace of the Peak. Situated as it is in the beautiful undulating country of the Peak district, with the River Derwent gaily swinging its way through the broad acres that comprise the Park, Chatsworth possesses more interest for those who study and appreciate gardening than perhaps any other place in the United Kingdom. Its historical associations are too well known to need repetition at this juncture;

rain in the district of the Peaks, we were able, under the courteous guidance of Mr. Jennings, the head-gardener, to see something of what are undoubtedly the most noble, if not the most pleasingly-designed, gardens in Great Britain. We must, however, first mention that the mansion and grounds are open to visitors three days a week from May till August. To many who have spent pleasant hours there it will come, perhaps, as a surprise to know that the pools in the famous Water Lily House have been filled in and the house converted into an orchard-house, and for protecting Chrysanthemums in the autumn. A notable feature is an avenue of closely pruned Tulip Trees that leads to the main entrance, the green foliage of these making a fine background for tall pyramids of scarlet Pelargonium Viscount Kitchener. These

Solomon's Walk, a broad pathway, skirting, as it were, the large expanse of lawn that lies at the south front of the mansion, the grass bank immediately below the walk having beds cut in its face to form a bold chain, with pendants at intervals of about twenty yards. At the time of our visit this chain was planted with yellow and white Violas, and the pendants with those of violet and lavender hues. To fill these and other beds no fewer than 20,000 Viola plants are required annually, these being obtained by means of cuttings planted early in the autumn.

Fountains, cascades and statues abound in the pleasure grounds, while ornamental ponds, filled with Water Lilies and other aquatics, meet the visitor at almost every turn. The water is obtained from the lake situated some 400 feet above the level of the gardens and right on the side of the towering hill, whence flows the wonderful cascade shown in the illustration on page 611. Then from the Wellington Rock, high up on the cliff side, water tumbles over jutting rocks to the pool below, thence wending a more peaceful way to the lake in the dell or natural garden near by, where Bulrushes, hardy Ferns and other native plants find a happy home.

Further up on the hillside, and stretching away from the mansion for a considerable distance, is the Arboretum, which includes many good and well-grown trees. Among these are the three Royal trees. One, an Oak, was planted by the late Queen Victoria, then Princess Victoria, in 1832. Planter and tree would be about the same age; the Oak is still in its youth, but the planter has, alas! been called to the Great Beyond. It is only by a comparison such as this that we realise how fleeting is the life of man. Another tree is a Spanish Chestnut, planted at the same time by the Duchess of Kent; and the third is a Sycamore, planted eleven years later by Prince Albert, who had then been Prince Consort for two years. Bordering the pathway that takes the visitor through the Arboretum is a babbling stream of crystal water some half a mile long, in which trout may at times be seen disporting themselves. Rhododendrons and other suitable shrubs and low-growing trees are effectively grouped by the margins of the stream. This bountiful and natural supply of water is of the greatest value to Chatsworth, and in

the Temple of Venus, near where the rill loses itself in the ground, the following descriptive poem is carved in stone:

Won from the brow of yonder headlong Hill,
Through grassy channels, see, the sparkling rill
O'er the chated pebbles, in its murmuring flow
Sheds freshness on the thirsty vale below.
Quick'ning the ground till trees of every zone,
In Chatsworth's soil, and clime, forget their own.

To the keen lover of plants the indoor gardens at Chatsworth are almost as interesting as the noble terraces and broad, carpet-like lawns that form such a feature of the outdoor gardens. Stretching up from the French Garden is the Portland Walk, which is a sort of corridor with glass roof and front. Here many interesting plants find a congenial home, among them being some fine old specimens of *Camellia reticulata*, Fuchsias, Acacias and other hard-wooded kinds. In the

CHATSWORTH, WHERE THE KING AND QUEEN ARE TO STAY NEXT WEEK.

but it may, perhaps, be necessary to remind the younger generation of our readers that it was here that Sir Joseph (then Mr.) Paxton exercised his art of landscape gardening, and the general lay-out of the gardens to-day is much as it was in his time. The design for the Crystal Palace, of which so much has been heard recently, was supposed to have been suggested by the Lily House that he designed at Chatsworth, and a comparison of the architecture of the two certainly appears to lend some colour to this theory.

We do not, however, propose to enter into useless discussions as to the correctness or otherwise of this supposition, nor to dwell at length on the work of Paxton, but rather to give a necessarily brief description of a few features of the gardens and pleasure grounds as we saw them one day in September. Although it rained as it can only

plants, which are grown in large tubs, are about ten feet high, and create a really wonderful and pleasing effect.

The Italian and French gardens at Chatsworth are both good examples of their kind, the former being planned on particularly bold lines. Here Irish Yews stand like sentinels on guard, with large beds filled with ornamental foliage and flowering shrubs as companions, broad walks leading to other and more remote parts of the gardens, branching off in several directions. In the French Garden, which is on a much smaller scale, the pillars supporting the statuary are wreathed with Rambler Roses, and the beds planted with white, purple, violet and pale blue Violas, the whole being so arranged as to provide a perfect harmony of quiet colours. Leading from the French Garden to the broad expanse of water beyond is the famous

THE CONSERVATORY AT CHATSWORTH, PROBABLY THE LARGEST OF ITS KIND IN THIS COUNTRY.

credit on those responsible for their cultivation. In one of the Peach-houses we were interested to see a very fine plant of the Persimmon (*Diospyros Kaki Pashomari*) that was bearing a very heavy crop of its pale orange coloured fruits. Unfortunately, owing to the proximity of the fruit-houses to the River Derwent, it is no uncommon occurrence for the stokeholes and floors to be flooded. This is, of course, a very severe handicap in the production of first-class fruit.

There are, of course, many other interesting features in the gardens at Chatsworth, but lack of space will not allow us to deal with them here. The average visitor will find it difficult indeed to get a full grasp of the noble and beautiful effects that abound so freely in these gardens, which have,

plant-houses near by, *Begonia Gloire de Lorraine*, Scented-leaved *Pelargoniums*, *Carnations*, *Heliotropes*, *Hydrangeas* and *Chrysanthemums* are grown in very large quantities, and at the time of our visit these were in particularly good condition. Special mention must be made of the *Carnations*, which are the favourite flowers of Her Grace the Duchess of Devonshire. Perpetual-flowering and *Malmaison* kinds are grown by the thousand, and we have never seen a finer lot of plants.

One of the principal features of Chatsworth is, of course, the large conservatory or winter garden, an illustration of which is reproduced above. This is probably the largest of its kind in any private establishment in this country, and the broad gravel path that runs through the centre is sufficiently large to enable carriages to be driven through with perfect freedom. Owing to the character of the plants in this house, the temperature has, of necessity, to be maintained much higher than is usual in conservatories. At each end of the house bold masses of rockwork have been skilfully arranged, with small pools nestling at their bases, the latter forming congenial homes for choice *Water Lilies*, the *Cape Pondweed* and many other kinds of aquatic plants. The rockwork itself is almost concealed by *Ferns*, *Selaginellas* and other dwarf forms of plant-life. In the broad borders on either side of the main pathway such plants as *Monstera deliciosa*, *Musa Cavendishii* (a *Banana* that fruits splendidly here), *Pouzrea coccinea* (with racemes of small, bright scarlet flowers), *Hedychiums* and many other unusual kinds are grown in quantity; hence

the visitor might well imagine himself to be in a semi-tropical country instead of in one of the most beautiful counties of England.

The fruit-houses are, naturally, of a very extensive character, and such kinds as *Peaches*, *Figs*, *Muscad Grapes* and choice dessert *Cherries* are very largely grown. We have seldom seen *Peach trees* in better condition than those at Chatsworth, and the *Muscad Grape Vines* were carrying very heavy crops of fruit, which reflected the greatest

through the kindness of the Duke of Devonshire, come to be regarded more in the light of a national asset than the private property of one of our oldest English families.

There are many lessons to learn at Chatsworth, and the student of English gardening could, with advantage, spend many days in this delectable place, where garden and woodland and water are successfully blended to make one harmonious whole.

COLOURED PLATE.

PLATE 1482.

THE LEPTOSPERMUMS.

THE *Leptospermum* are a genus of shrubs belonging to the Myrtle family, natives of Australia and New Zealand. Some members have been long grown in gardens, where they are remarkable for their great profusion of blossoms, which, until the introduction of some of the newer forms of *Leptospermum scoparium*, were in most cases white, or nearly so. While the different kinds must be looked upon as greenhouse or conservatory plants over the greater part of this country, they form handsome outdoor bushes in the favoured parts of these islands, such as in the South-West of England and the corresponding portion of Scotland. In parts of the Sister Isle, too, they are equally at home, and justly valued for their beauty when in bloom.

The oldest and best-known member of the genus is *Leptospermum scoparium*, which occurs in great profusion in a wild state both in Australia and New Zealand. One of its popular names is Captain Cook's Tea Plant, owing to the leaves having been used for tea by that intrepid navigator during his voyage round the world. Another name by which it is known in its New Zealand home is Manuka, concerning which the late Mr. John Gould Veitch, in his "Traveller's Notes," writes: "For many miles we drove through a dense growth of Manuka (*Leptospermum scoparium*), described as the most common plant in the Colony. It covers hundreds of acres, ranging from half a foot to 30 feet in height, and is said to be very effective from November till January, when it flowers in great profusion; at other times the acres of peculiar grey green are apt to weary the eye." Of *L. scoparium* the variety *grandiflorum* has been known for over a century. This has larger flowers than the type, and they have, in addition, a rosy tinge. It is not much grown; indeed, the extreme variability to be found among the different forms of *L. scoparium*, as shown last year at the International Horticultural Exhibition held at Chelsea, took a great many by surprise.

At that time the variety *Nicholli*, of which a coloured plate is given with this issue, made what must be regarded as its first public appearance, and from its distinct character and great beauty it created quite a *furor*. Not only did it attract the attention of the general public, but it was awarded a first-class certificate by the floral committee, and, furthermore, gained the cup for the best new plant in the show. As it is such a real good thing, some account of its early history will,

no doubt, be interesting. On the authority of Captain A. A. Dorrien-Smith, this remarkable variety originated on the sandhills a little north of Christchurch, New Zealand, and was apparently derived from the white-flowered forms which alone occur in its immediate neighbourhood. It was taken in hand by Messrs. Nairn and Sons, nurserymen, Christchurch, and by 1908 a fair stock had been obtained. Apart from the rich colour of its blossoms, the leaves are also very deeply tinted. This variety is stiffer in habit than the typical *L. scoparium*, while another, of even more upright growth, was shown at the same time and given an award of merit. This was *Chapin-nuit*, whose

Since *L. s. Nicholli* gained such high honours it has been much sought after and now finds a suitable home in a few favoured gardens. It is said to come reasonably true from seed, and, as with the other members of the genus, cuttings are not at all difficult to root.

Of the other species of *Leptospermum*, perhaps the best known is *L. bullatum*, a free-growing, compact, little bush. Good flowering examples of this may be grown in pots 5 inches or 6 inches in diameter, and in this way they form useful decorative plants for even the small greenhouse. This by no means exhausts the list, but the following are very rarely met with: *L. ericoides*, *L. flavescens*,

L. levigatum, *L. myrtifolium*, *L. pubescens* and *L. stellatum*.

Propagation and Culture.—As above mentioned, *Leptospermum* are not at all difficult to increase by means of cuttings. These should be formed in early summer of the half-ripened shoots, which, if dibbled into pots of sandy soil and placed in a close propagating-case kept rather warmer than the temperature in which they have been grown, will soon root. A mixture of loam, peat and sand will suit them well. Potted off singly when sufficiently rooted, they must be stopped two or three times during their earlier stages in order to ensure a bushy habit of growth. Besides cuttings, seeds often ripen, and from these young plants can be raised in quantity, as each capsule contains, generally speaking, a considerable number of seeds. Established plants employed for the decoration of the greenhouse or conservatory should, after flowering, have the shoots shortened back if necessary, and any old and exhausted wood in the middle of the specimen thinned out. If repotting is needed, it must be done as soon as the young shoots are about half an inch in length. The compost of loam, peat and sand should be fairly rough and pressed down firmly. If the plant or plants do not require repotting, an occasional stimulant will be very beneficial during the growing season. Throughout the summer the plants may be stood out of doors, taking care that they are well supplied with water.

H. P.

The coloured plate was prepared from a spray kindly sent us by Mr. James Coey, Donard Nursery, Newcastle, County Down, Ireland.—Ed.]

THE WHITE FLOWERED ABUTILON BOULE DE NEIGE.

flowers have not the richness of colouring of those of *Nicholli*, but are more of a deep rose or rosy red tint. It was discovered as an individual plant in the South Island of New Zealand some years before *Nicholli* was found. A third variety, and an exceedingly graceful one, was shown at Chelsea at the same time as the others. This was *Boscawen*, whose flowers are unusually large, and white with a reddish centre. The unopened buds are brightly coloured. It may be noted that these three beautiful and distinct varieties were then shown by the Rev. A. T. Boscawen, Long Rock, Cornwall.

ABUTILON BOULE DE NEIGE.

ALTHOUGH an old variety, this is still one of the best white *Abutilons* as a greenhouse climber. It is seen to best advantage when trained to roof rafters or when tied loosely to greenhouse pillars. Throughout winter it provides a succession of flowers, borne gracefully on slender stems. The white petals are delicately veined or netted, to which the golden anthers of expanded flowers form a pleasing contrast.

NEW FLOWERING SHRUB:
"Leptospermum Nicholii."

GARDENING FOR BEGINNERS.

LILIES FOR OUTDOOR BORDERS.

IN all we have about sixty species of *Liliums*, or Lilies, cultivated in our gardens. Some twelve to twenty of these will grow in the soil one meets with in the borders of most gardens, flowering freely in the broad, extensive borders of a large country garden, or the narrow border of the town and suburban garden. Lilies may be associated with herbaceous and other plants in the perennial or mixed borders, while they will be found to thrive equally well in the shrubbery border. A few groups planted between the shrubs where space permits give added interest to the border, and brighten it up considerably when the Lilies are in flower. From these few remarks it will be gathered that the beginner need have no hesitation in taking up Lily culture. It will be found a most interesting subject, both on account of the different kinds being so varied in habit, the colour and size of the flowers, and from the fact that outside in the border a dozen kinds will provide a succession of bloom from the end of May to October.

The most general method of increasing Lilies is by means of offsets, the bulbs with age dividing up and producing several growths. These may be carefully separated when the stems die down in the autumn or winter when the weather is open. Several Lilies, notably the Tiger Lily, produce bulbils in the axils of the leaves. These, if carefully removed when mature and placed in boxes

of sandy soil, or dibbled in a sheltered border outside, will flower in two or three years. Raising Lilies from seeds is a rather fascinating occupation, which may be quite satisfactorily carried on with only the help of a cold frame. The plants flower in from two to four years, only the Giant Himalayan Lily, *Lilium giganteum*, taking, as a rule, longer than this.

Planting Lily Bulbs.—The depth to plant the bulbs of Lilies depends on their size and whether roots are produced on the base of the stem immediately above the bulbs as well as below, or only from below the bulbs. Examples of a stem-rooting Lily, *L. speciosum*, and *L. pardalinum*, a non-stem-rooting Lily, are illustrated. These serve to show quite well how necessary it is to plant

the bulbs of the stem-rooting Lilies much deeper in the ground. A selection of Lilies suitable for the beginner, which may be expected to thrive and flower freely in most gardens, is as follows: Stem-rooting—*L. croceum*, *L. elegans*, *L. Hansonii*, *L. Henryi*, *L. longiflorum*, *L. speciosum*, *L. tigrinum* and *L. umbellatum*. Non-stem-rooting—*L. candidum*, *L. chalcedonicum*, *L. Martagon*, *L. monadelphum*, *L. pardalinum*, *L. pomponium*, *L. pyrenaicum* and *L. testaceum*. Large bulbs, such as *L. Henryi*, which produce quantities of stem-roots, should be covered with 8 inches of soil; bulbs of moderate size, *L. tigrinum*, 6 inches; and small bulbs, *L. elegans*, 4 inches. Large bulbs with no stem-roots, *L. pardalinum*, 3 inches to 4 inches of soil; small bulbs, an inch less. In cottage gardens we sometimes see the Madonna Lily, *L. candidum*, with its bulbs growing on the surface, in excellent condition, apparently unharmed by frost or any other weather conditions.

The second illustration depicts the method of planting Lilies in groups or clumps. The six bulbs are those of *L. umbellatum*. The hole is 2 feet across and 8 inches deep, so that when the bulbs are placed on the bottom they may be covered with 6 inches of soil. In planting Lilies, particularly if the soil is heavy, it is an excellent plan to surround the bulbs with coarse sand, placing a layer in the bottom of the hole previous to putting in the bulbs, and another on the top before covering in with soil. This assists drainage immediately around the bulbs. The roots of Lilies will be found to reveal in flaky leaf-mould, a little of which may with advantage be incorporated with the soil when planting. With the

2.—LILY BULBS PLACED IN POSITION AND READY TO BE COVERED WITH SOIL.

exception of *L. candidum* and *L. testaceum*, which should be planted in August, all the Lilies named may be planted at the present time. It is also safer to pot up the bulbs of *L. speciosum* and *L. longiflorum* if newly-imported Japanese bulbs are purchased.

L. chalcedonicum, the Scarlet Turk's-cap Lily, 3 feet to 4 feet high; flowers in July; best in sunny herbaceous border; rich loamy soil.

L. croceum, the Orange Lily, 3 feet to 4 feet; flowers June and July; loamy soil, in herbaceous border.

L. elegans, also known as thunbergianum, flowers during May and June; 1 foot to 2 feet high; several sorts with yellow, orange, apricot and crimson flowers. Plant along the front of a shrubbery border where the plants will get a little shade about midday. Add a little peat to the soil when planting.

L. Hansonii, yellow, drooping, spotted flowers, 3 feet to 4 feet high; flowers in June; herbaceous or shrubbery border.

L. Martagon, light purple spotted flowers, 3 feet to 4 feet high; flowers June and July; delightful in the borders and wild garden. The white variety, *alba*, is one of the most beautiful of all our garden Lilies, producing stems 4 feet high, with twenty or more waxy white flowers.

L. monadelphum, also known as *szovitzianum* and *colchicum*, rich straw yellow flowers, 4 feet to 5 feet high; flowers in July; a good Lily for the herbaceous and mixed border.

L. pardalinum, orange spotted flowers, 5 feet to 7 feet high; flowers during July and August; plant in shrubbery border, using a little peat.

L. pyrenaicum, yellow, spotted black, 2½ feet to 3 feet; flowers May and June; shrubbery border and wild garden or herbaceous border, the first Lily to flower outside.

L. tigrinum, the Tiger Lily, orange spotted flowers, 4 feet high; flowers in August; *Fortunei giganteum* flowers in September and October; grows 5 feet to 6 feet high; herbaceous border.

L. umbellatum.—There are several varieties with orange, red, or crimson flowers, 2 feet to 2½ feet high; flowers in June and July; plant in herbaceous or shrubbery border.

A. O.

1.—THE STEM-ROOTING LILY ON THE LEFT SHOULD BE PLANTED DEEPER THAN THE NON-STEM-ROOTING LILY ON THE RIGHT.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Flower Garden.

Plants in Frames.—These must be regularly picked over, as, wherever a decayed leaf comes in contact with a sound one, the latter is sure to become contaminated owing to the great amount of moisture at this season of the year.

Fuchsias.—Where spring-struck plants are relied upon for filling vases in the flower garden and for bedding-out purposes, an early start is necessary. A few stock plants should be partly cut over and placed in a moderately warm house where they may be lightly sprayed over. Here they will soon break nicely, and if kept in a light position, good, sturdy cuttings should be ready for rooting early in the year, and quite good plants are thus obtained by the time they are required.

The Pleasure Grounds.

Hypericum perforatum.—The common St. John's Wort is a very useful plant about the pleasure grounds, as it may be utilised in a number of positions where other plants will hardly grow, much less thrive. On borders under trees, once it becomes established, it will form a fine green groundwork, which looks very much nicer than the bare soil. Under large, isolated trees, where grass will not grow, this plant will do well, and if small plants or offsets are planted about nine inches apart any time during the winter, they will quickly establish themselves, and though they may not flower so freely as in a more open position, they will at least look green the whole season through. By cutting down early in the spring and giving the ground a slight dressing of manure, growth is accentuated. For edging large beds of shrubs it is also useful, while steep banks may be furnished with it after many other subjects have failed to grow at all.

Plants Under Glass.

Chrysanthemums.—By this date cuttings should be in a good condition for propagation, and though I am convinced that very early propagation is not actually necessary, it is quite wise to make a start with those varieties that require a long season of growth. Bob Pulling, Queen Mary, Hon. Mrs. Lopes, Amber Queen, Mme. P. Radaelli and its sports, Edith Jameson and its sports, Mrs. R. C. Pulling, Fred Chandler, Fred Green and Miss A. E. Roope are best on first-crown buds, and in each instance these have to be secured fairly early.

Decorative and Single Varieties as they are cut down may be put in cold frames, as these need not be propagated before the month of February.

Forcing Plants, such as Azalea mollis, Lilacs, Prunuses, Laburnums and Viburnums, may now with advantage be brought indoors, and though it is not advisable to give too much heat to commence with, a temperature of 50° at night, running it up with sun-heat during the day, will soon put them into growth, when a little more heat may be employed. In medium-sized establishments it is not convenient to devote a house entirely to these forcing plants, but they will be found to do quite well in a vinery or Peach-house that has been shut up, removing them eventually to the flowering house or conservatory.

The Kitchen Garden.

Seed Potatoes that may be required for very early work in pots or heated frames may with advantage be stood in boxes and placed in a light position, when sprouting will commence. At this season they do not push so quickly; hence the necessity of preparing them some time beforehand.

Hot-beds.—These are best made up in brick pits at this season, and should be well trodden down. A good proportion of leaves will tend to increase the lasting qualities of the hot-bed. Carrots are the first crop that should be sown, and for these from 6 inches to 9 inches of soil should be placed on the fermenting material. If the soil comes to within 1 inch or 2 inches of the glass, so much the better, as it is sure to sink considerably before the crop attains any great height. Sow as soon as the soil is in condition, and keep the frames fairly close till the seedlings

appear through the soil. The frames must be covered in severe weather, though nothing short of frost will actually hurt the Carrots.

Fruits Under Glass.

Pot Figs.—Where these are utilised for very early crops, the trees should now be thoroughly cleaned, afterwards giving them a good dressing of Gishurst or some other insecticide. This is especially necessary where the trees are infested with scale. The house in which the trees are to be grown should also be thoroughly cleansed before starting the Figs. A steady temperature of between 50° to 60° should be maintained till the leaves commence to push, when the temperature may be raised from 5° to 10°. Bottom-heat is not absolutely essential for pot Figs, but for early work it is certainly beneficial. Too much water at the roots should be avoided, though at no time should the roots become at all dry after the plants are started, and a fairly humid atmosphere must be kept up by lightly spraying and damping, reducing it somewhat in the event of very frosty weather.

Hardy Fruits.

In addition to the usual small fruits, such as Black, Red and White Currants, Gooseberries, Blackberries and Loganberries are fruits that are well worth more consideration than they often get. It may be urged that Blackberries are very easily secured in the wild state right out in the country; but there are many gardens where this does not apply, and I know of no fruit which is more appreciated and, I might add, remunerative than the Parsley-leaved Blackberry. Once established, it will go on fruiting for years; but, like everything else, it must be given a fair amount of manure either in the winter or, preferably, when the fruit is set in the autumn. The Loganberry also is very useful, and as it goes on cropping after the bulk of the Raspberries are over, it should be cultivated in every garden. I find it soon gets tired of one position in the garden, so young plants should be put in fresh positions every four or five years. The present is a good time to plant both of these subjects, and, providing the soil has been well worked, practically any position in the garden will suit them.

THOMAS STEVENSON.

(Head-gardener to E. Mocatta, Esq.)

Woburn Place Gardens, Adlestone, Surrey.

FOR NORTHERN GARDENS.

The Flower Garden.

Wheeling Manure.—Any necessary wheeling of manure or soil, either for improvements or routine work, should be done during frosty weather if convenient, and where this is not possible, planks should be laid for wheeling beyond the walks.

Carnations.—Where these have the benefit of a frame, they should be kept rather dry and a sharp look-out be kept for mice; and, if they appear, they must at once be trapped or treated to a little Rodine on the top of buttered bread.

Herbaceous Flowers.—Materials for top-dressing should be got ready for application in the spring. Decayed leaves, old potting soil and vegetable mould are all suitable, and if they are mixed now and formed into a conical heap, they will be in good condition when wanted.

The Smaller Gladioli.—These are now to hand, and if the ground is ready or is in working order, it is as well to plant them now and afford them some protection, as February is often a wintry month in Scotland, and if planting is delayed beyond that, a proportion of the combs often perish. The following are desirable varieties: Ackermannii, Blushing Bride, Colviller alba, C. rosea, Ne Plus Ultra and Peach Blossom.

The Rose Garden.

Planting Rose Hedges.—The ground should be well trenched, and the plants be put zigzag in a double line at about two and a-half feet apart in the line. After being planted they should be headed down to from a foot to 2 feet, according to the class. Afterwards they will require little attention beyond keeping them free from weeds and any extra vigorous shoots in check.

The Rock Garden.

Mice.—It is no uncommon thing for mice to ensconce themselves in the cosy corners of the rock garden during the cold, wet winter weather, and when wintry conditions obtain they are nothing loth to nibble at some favourite plant and make short work of it. One cannot, therefore, be wrong in keeping one or two "Gert" traps, baited with a little piece of cheese, in those same cosy corners.

Plants Under Glass.

Propagating Chrysanthemums.—The work of propagating the large-flowered Japanese varieties must now be proceeded with. The cuttings should either be taken from suckers or from as near the base of the stem as possible. Few growers strike them singly in 2½-inch pots nowadays, but dibble them in rather thickly in pots 4 inches or 5 inches in diameter. A suitable compost to use is equal parts of loam, good leaf-mould and sharp sand, finishing with a thin layer of sand. The pots should, of course, be very thoroughly drained. Stand the pots in a propagating-frame, and, although opinions differ, I think it is better not to cover with glass, but leave them exposed. I admit that by doing so they will take rather longer to root, but one will probably not lose a cutting through damping, and the young plants will be sturdy from the start. Place them in a greenhouse temperature and give just sufficient water to keep the soil from becoming actually dry.

Cyclamens.—These attractive flowers are at present a valuable asset, both for conservatory decoration and for filling small vases. When picking the blooms, they should not be cut, but pulled out by means of a twist or wrench. They last a long time in the cut state.

Fruits Under Glass.

Pruning Late Vines.—As soon as Gros Colman, Black Alicante and Lady Downe's have shed their leaves, they should be pruned. Where long spurs have been allowed to form on the rods, each alternate one should be cut back with a fine saw, and the cut afterwards dressed with a sharp knife. In pruning, only one or two eyes should be left, as only one can ultimately be retained.

Pot Vines.—Before starting these see that the drainage is all right, and if the presence of worms is suspected, give a watering with clear lime-water. Remove a little of the surface soil by means of a pointed stick, and give the plants a good top-dressing with turfy loam and Thomson's Vine Manure, after which give a good watering. It is an excellent plan to stand the pots on an inverted turf, but there is no need to do this till the roots become active. If placed under too soon, the turf is apt to become sodden before the roots are ready to lay hold of it.

The Hardy Fruit Garden.

Loganberries.—If the double trellis system is pursued, the succession canes will have been tied in position as growth has proceeded; still, it is necessary to overhaul the plants after they have become defoliated. Head back any shoots which have gone beyond the desired limit, cutting away all laterals, after which examine the shoots and finish any tying of them that is necessary.

Raspberries.—If these are trained to stakes, they should be examined, and any which have become decayed should be replaced by new ones, after which any superfluous canes inadvertently left should be cut away. Five canes are quite enough to leave at a stool. When subsequently tying in the shoots, do not tie them hard to the stake.

The Vegetable Garden.

Protection from Frost.—It should be borne in mind that while Jerusalem Artichokes, Parsnips and Leeks are quite hardy, they cannot be dug up during severe frost unless a portion of the crop has been covered with some loose litter as soon as such a condition threatens. The alternative plan is to lift a portion of the crop and store it in a cellar or shed among sand. Celery must, of course, be protected from frost, or serious damage to the crop will result.

Brussels Sprouts.—This crop is a valuable asset during the winter, but if a portion of the crop is allowed to remain after picking is finished, the growing tops will prove very useful in spring before early Cabbages turn in.

THE ROSE GARDEN.

IN A HAMPSHIRE GARDEN.

SOME OF THE NEWER DECORATIVE ROSES

(Continued from page 508.)

WHAT is a decorative Rose? In the old days, say twenty years back, anything in the shape of a Rose that was not up to exhibition standard was termed a "decorative" or "garden" Rose, and that to a certain, although undoubtedly to a less, extent is still true. But the time surely has come when a standard as stringent I would almost write more stringent—should be set up for our garden or decorative Roses. With the exhibition Rose much may be, and is, forgiven if the flower conforms to a certain orthodox standard. It may be lacking in scent, it may be of weak or deficient constitution, very shy-flowering, of bad habit of growth, even be of a bad colour, and yet still be a good exhibition variety. Now, none of these various defects can be allowed in a good garden Rose. It must have perfume, be of strong and vigorous constitution, of free-flowering nature spread over a long period, of a good habit of growth, and, lastly, must be of a fine and pleasing colour. The almost only characteristic that it need not have is a uniform or symmetrical shape. Which standard is the more difficult to obtain? Undoubtedly that suggested as the one to adopt for the garden Rose. A standard is necessary. Perhaps the National Rose Society will look into the matter at the same time as they tackle the question of classification. The two are very much alike; in fact, a solution of the one will almost solve the other. We do not want a Rose that is neither the one nor the other, not good enough shape for exhibition purposes, and lacking fragrance or some equally important feature, and so making it undesirable for decorative purposes. I am sure if the National Rose Society would only tackle the question boldly, they would earn the grateful thanks of all concerned, trade grower and Rose purchaser alike. Something will have to be done, for the number of varieties is getting legion. As long as the public ask for the old varieties that have been superseded by better varieties, the nurserymen will grow them. I am glad to see that Messrs. Alex. Dickson and Sons are doing something to meet the difficulty. After a detailed list of Hybrid Perpetuals covering three pages, they give a further list of names, stating the following can be supplied; but in my opinion much better varieties are to be found in the preceding pages. I think these can very well be done without, and I presume in due course they will not be grown. I should like the National Rose Society to draw up a list of Roses "we can do without," and I am afraid among them would have to be included many new as well as many old varieties.

In dealing with the newer Roses in a kind of general review, I mentioned certain varieties as the best of their colour, and I do not, therefore, propose to refer to these again unless they call, as some few of them will, for special comment. I do not think there are any Hybrid Perpetual Roses either new enough or good enough to be referred to. Rouge Angevine is a very fine colour, but has an awkward habit of growth, and is *scentless*; this in a red Rose is unforgivable. With regard to the Hybrid Teas, the story is very different. I will try to keep them in alphabetical order.

Bertha Gaulis (Dr. Bernax, 1910) has proved very free-flowering and a good grower here. Colour, deep china rose; good shaped flowers, and not subject to mildew. Nice long bud.

British Queen (S. McGredy and Son, 1912) I have already referred to. The flowers last a very long time, both on the plant and when cut. Of very similar habit of growth to Mrs. Herbert Stevens; in fact, it might have been sent out as a Tea without anyone grumbling.

Carine (Alex. Dickson and Sons, 1911). One of the favourites in my garden here. The long and elegant shaped buds are all the colours almost of the rainbow, make delightful button-holes, and a most beautiful table decoration; but it is at its best in the garden. A plant of it with buds and flowers in all stages of growth is a glorious picture. One of these days I hope to have a bed of it. An excellent grower, carrying its flowers erect on long footstalks. Strongly perfumed, with fine foliage. It is altogether a delightful Rose. I have not named its colour, because I cannot. No two flowers, unless they are of the same age, are alike, and one gets shades of cream, fawn, orange with carmine markings, bluish and pale salmon pink all on the plant at once. A decided and distinct acquisition to our garden Roses.

Dorothy Ratelife (S. McGredy and Son, 1911). Medium-sized flowers, probably a Lyon cross, yellow and fawn, shaded coral. A beautiful Rose, but surpassed by the nursery's newer varieties Mrs. C. H. Pearson and Mrs. F. W. Vanderbilt. It makes a good bedding variety.

Duchess of Wellington (Alex. Dickson and Sons, 1909)—A tall grower, after the style of Killarney, tree-flowering, deep saffron yellow in colour, flowers fairly full, delightful fragrance. A good variety.

Edith Part (S. McGredy and Son, 1913).—I see the National Rose Society's new catalogue (1914 edition) calls the colour of this Rose honey yellow. This is a mistake. The flower is really a bicolor, rich brick red almost, on the outer petal a colour that nearly comes through the flesh or pink of the inside of the petal. A particularly striking Rose, flowers medium size, but very freely produced, a good grower, mildew-proof, deliciously scented, of fine habit. Really a continuation of the same colour-scheme that runs through Grand Duc de Luxembourg, Mrs. E. G. Hill, Lady Alice Stanley and similar Roses, only in this case very much intensified. I have never seen any yellow, honey or otherwise, in this flower, and I have grown it now for two seasons and saw it in full flower at Portadown in 1912.

Entente Cordiale (Pernet-Ducher, 1909).—This is quite a good Rose, of a creamy white, shaded yellow at the base of the petal, an excellent shape and a free-flowerer. It should make a good bedding Rose. Unfortunately, another Rose has a similar name, but that other Rose is little better than a weed, and certainly not worth growing.

Florence Haswell Veitch (William Paul and Son, 1911).—Almost a pillar Rose, at any rate a pretty vigorous dwarf. Very fine colour, brilliant scarlet, very fragrant and fairly free-flowering. Not very large, but of good shape.

H. E. Richardson (Hugh Dickson, 1913).—A gold medal Rose, awarded at Belfast last year. A miniature Victor Hugo, beautiful shape, very fine colour, vigorous free growth, and I hope will make a fine bedding Rose. As shown by the raisers a very beautiful variety.

Southampton HERBERT E. MOLYNEUX

To be continued.)

NURSERY NOTES.

MESSRS. WILLIAM ARTINDALE AND SON.

It is not uncommon to find that people who dwell in the metropolis, its nearer suburbs and the Home Counties, think the area covered and with which they are more or less familiar represents the universe. They pride themselves upon the impurities of the atmosphere and upon the delightful scenery of many places within the sound of Bow Bells. They rest assured in their own minds that the nurserymen who shine in the limelight of the Royal Horticultural Society count, while those who seldom come to the "Hall" are lesser luminaries of another and a poorer world. They are wrong on many points. The prevailing conditions of the atmosphere of Birmingham, Manchester, Sheffield and other of our great provincial cities would do credit to the best London particular that can be remembered by living man, and the environs of these places are at once a source of pleasure and wonder to the visitor who has become imbued with orthodox metropolitan notions. It is quickly found, too, that some of the provincial nurserymen who do not honour the Hall frequently have establishments equipped and stocked in a manner that would do credit to the finest of those who always contribute exhibits, but they do not come regularly because they cannot justify the enormous expense entailed.

Among such as these rank Messrs. William Artindale and Son of Sheffield. The address may, at first glance, appear rather vague. The firm has depôts and warehouses in several parts of the city, and at the moment it is proposed to direct attention to one only—the nursery at Nether Green, beyond question one of the most charming suburbs of which any town or city in England can boast.

When in Sheffield in the late summer to see a local show, a few spare hours were promptly devoted to a visit to Nether Green in the anticipation of seeing a small, provincial nursery. The realisation was, however, quite different from the anticipation, since the place proved to be splendidly maintained, and stocked with such a comprehensive collection of hardy plants as would turnish ready and excellent material for furnishing completely a garden of exceptional extent. The ground stands on the higher slopes of a hill, and is divided into many quarters of varying sizes to afford proper accommodation for the many scores of plants demanding different requirements. Tall hedges separate the quarters or drifts, and within them the features at the particular moment of this visit were the Sweet Peas and the Violas.

Of the first named there were dozens of magnificent rows in full bloom at a time when our own in the South were fast assuming the sere and yellow. All the finest new varieties were seen in splendid form, and those old ones that must still rank among the best were also grown in bulk. They were 8 feet to 10 feet high under ordinary culture, which says much for the excellence of the soil and the cleverness of the management to which they are subjected. The primary object was the production of bushes of blooms for sale in the firm's shops in the city, but they had also yielded hundreds of superb bunches for exhibition at shows all over the provinces.

The feature of the time was, however, the Viola garden, which presented a picture the splendour of which

could not easily be found anywhere in the world, and assuredly could not be excelled. Great beds, each filled with one variety, were carpets of handsome blossoms, embracing all the hues and shades now found in these beautiful plants. Some varieties were more floriferous than others; some plants grew more vigorously than others; but the comprehensive display was perfect. There are some five hundred thousand plants grown here, and sixteen medals have been awarded them at various shows this season. To mention only a few, and these not necessarily novelties, there were: Mrs. William Artindale, bronzy purple centre, shading mauve and splashed violet; J. H. Watson, reddish purple, striped magenta and white; Ajax, pinkish white, very large; Crimson Bedder, deep pink; A. J. Bastock, purple rose, striped light rose, large; Charles B. Murray, bright purple, streaked rose, large and handsome; Agnes Kay, white centre, almost rayless, edged heliotrope; Edina, dark blue; G. C. Murray, bottom

seen even in big establishments, would have to be named, and the notes would consequently resolve themselves more or less into the form of a catalogue. Space is too valuable in *THE GARDEN* for that. Suffice it, therefore, to say that any plant worth a place in the choicest collection can be procured from Artindale of Sheffield.

We noticed a very large collection of alpine plants—not miniature roots, but thousands of good clumps, which, we were assured, were the ordinary size they supply. Large plots were also devoted to herbaceous plants, and the firm rightly boasts of a fine collection of Phloxes, Peonies, Pyrethrums, Primulas, &c.; while there were large plantations of early-flowering Chrysanthemums (of which 30,000 were sent out last spring) and Dahlias. The firm has also a branch nursery at Boston, where they grow Roses and many other hardy plants.

The glass department is not allocated to decorative plants, but to such as will produce crops for

ANSWERS TO CORRESPONDENTS.

FLOWER GARDEN.

PLANTING HERBACEOUS BORDERS (*Letter of Horticulture*).—You cannot do better than arrange the plants in groups, say, about three or six to each group, and thus create an effect impossible in any other way. In the wider portion you would have room for about three sets of groups, and in the narrower part two groups. This arrangement does not take any more plants than that of planting solitary specimens, and by employing select colours a more decided effect results. By arranging the groups alternately, more room is given them, and the surface soil is better furnished. Unfortunately, you say nothing of the nature of the soil, whether light or heavy, and this would have been helpful. For the back row employ single and double Sunflowers, particularly Helianthus multiflorus and H. in flore pleno; Delphiniums Amos Perry, La France, Duke of Comaucht, Mrs. Creighton and King of Delphiniums; also the following Michaelmas Daisies: Aster cordifolius Ideal, c. Perfection, Nova-Englie Mrs. Rayner, N. A. pulchellus, N. A. Mrs. S. T. Wright, Beauty of Colwall, Feltham Blue and Chimæ. By allowing a yard for each of these, the total length would be occupied. The second, or middle, row should contain Phloxes in pink, scarlet, and white and blue shades, also Anemone japonica in white, pink and red, Aster ericoides Desire, A. Novi-Belgii densus, A. diffusus horizontalis, Helenium cypricum, Trollius, Gallardias, Oriental Poppies, Aquilegia chrysantha, single and double Pyrethrums, Flag Irises in variety and others; while the front row might contain Hepaticas, Anemone sylvestris, Helenium pumilum, Phlox canadensis, Peonia tenuifolia fl. pl., Christmas Roses, Campanula carpatica alba, C. c. Riverlea, C. White Star, C. muralis, C. Hendersonii, alpine Phloxes, Narcissus Emperor, N. Empress, N. Sir Watkin, N. Barri conspicuus, Theris sempervirens and others. In existing circumstances you would find it a great help if you purchased "The Hardy Flower Book," by E. H. Jenkins, which is obtainable from our Publishing Department for 2s. 10d., post free. The book not only contains plans showing the arrangement of the plants, but is replete with lists giving their height, colour and time of flowering. You would find it invaluable.

THE GREENHOUSE.

SOIL FOR CHRYSANTHEMUMS (*G. D. R.*).—On no account use peat in the culture of Chrysanthemums, the main staple required for the potting compost being good fibrous loam.

DWARF WHITE JAPANESE CHRYSANTHEMUMS TO FLOWER IN NOVEMBER (*Ullockley*).—Ivory is a good white that makes a capital bush; Money-maker is a beautiful cut-flower variety; Pearson's White is a useful white sport from La Triomphante; and Felton's Favourite is a well-known market white for November cutting.

INJURY TO PELARGONIUMS (*Ignoramus*).—The trouble with the Pelargonium leaves appears to be mainly due to the plants having been grown in a moist atmosphere for a time and afterwards exposed to a rather drier one. We do not think you need fear any trouble with them. The Cinerarias are attacked by green fly. Thoroughly fumigate the house or frame in which they are growing so as to keep this pest in check. Cinerarias are very subject to it and need frequent fumigation.

PROPAGATING PERPETUAL-FLOWERING CARNATIONS (*L. R. D.*).—You do not say what facilities you have for the propagation of the Perpetual-flowering Carnations, as where proper appliances exist they strike root very readily. With regard to the sand, ordinary silver sand is usually employed, though builders' sand will do if sifted finely and free from impurities. If you have but an ordinary greenhouse in which to strike the cuttings, perhaps you have a small propagating-case in the warmest part available for the purpose. Failing this, a box about six inches deep and placed, if possible, over the hot-water pipes, will do. Provision must be made for drainage by boring some holes in the bottom, over which must be placed some broken crocks. Then put on a good layer of sand, into which the cuttings must be inserted. After this a good watering must be given through a fine rose, and when the superabundant moisture has dried up, the box must be covered with a sheet of glass. This should be taken off every morning and, if necessary, left on for a time in order to dry the foliage, as, should this not be attended to, the leaves may decay. Directly the cuttings are rooted, the glass must be removed. When put in they must be shaded from very bright sunshine. Where there is a handlight or small propagating-case available, the cuttings may be inserted in pots, putting ten cuttings around a pot 3 inches in diameter. The same general treatment must be observed. The best cuttings are furnished by the short-jointed side shoots; those that show a tendency to flower must be avoided.

TREES AND SHRUBS.

TO DESTROY AN OLD IVY ROOT (*G. D. S.*).—The large Ivy stem may be destroyed by exposing a few of the main roots, being holes three parts of the way through and filling them with corrosive sublimate in solution. A hole slanting downwards and half an inch or three-quarters of an inch in diameter may be bored in the stem and treated in a like manner. Common household salt may be used for the same purpose as the corrosive sublimate, but it does not act quite so quickly.

SOME OF THE VIOLA-BEDS IN MESSRS. ARTINDALE'S NURSERIES AT NETHER GREEN, SHEFFIELD.

and side petals black, top petals sky blue; Gladys Finlay, pure white, rayless, with a clearly-defined purplish blue margin; Lady Knox, primrose, large; Maggie Mott, soft mauve; Moseley Perfection, rich yellow, superb; Mrs. T. W. R. Johnston, upper petals mauve, under petals shining black; Mrs. Morrison, dark mahogany, striped pink and rose, with a prevailing bronze sheen; Kathleen, white ground, delicately suffused blue, with a heavy purplish red edge; and James Billing, white, broadly edged lavender. These are a few of the many and might form the nucleus of a splendid collection. Bidens dalhoides was an attractive hardy plant, with pretty pink flowers resembling the Cosmea on long stems, which flowered freely from June till October.

To mention the hundreds of other plants seen in perfect condition would simply mean that all the most popular kinds, as well as those of unquestioned merit and charm which are not so frequently

side in the shops, and the three features of outstanding merit were Tomatoes Pioneer and Prohific, both raised by the firm, and which are remarkable for the freedom and persistency with which they yield fruits of perfect table size and quality, and the strain of Primula obconica gigantea, for which Messrs. Artindale are famous. There were perhaps 5,000 plants, with flowers varying in colour from pure white to deep crimson and as large as a five-shilling piece, and orders for plants were being despatched to many distant places, while seed orders for these are often received from South Africa and other countries. The nursery reflects credit not only upon Messrs. Artindale and Son, but also upon their capable and courteous manager, Mr. Lewendon. We presume that the firm would be pleased to welcome any of our readers who happened to be in the district at any time during the spring, summer, or early autumn months.

EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return unaccepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Office: 29, Tavistock Street, Covent Garden, W.C.

NOTES OF THE WEEK.

Maidenhair Ferns for Cutting.—Where fronds of the well-known *Adiantum cucucatum* are in great demand for cutting, it is a good practice to cut a few plants completely down and allow them to get somewhat dry at the roots, afterwards placing them in a temperature from 60° to 70°, when they will soon push up new fronds, which as they grow may be gradually hardened off before cutting. If occasional batches of this valuable foliage plant are treated in this manner, good fronds may be obtained throughout the year.

Snowdrops in the Rock Garden.—Species of Snowdrops, such as *Galanthus caucasicus*, *G. elwesii*, *G. imperati*, should find a place in the rock garden, as they help to brighten it up during the dull days of winter. The first named blooms during most of the winter, and *G. elwesii* flowers quite a fortnight before *G. nivalis*, the common Snowdrop. Where any of these are already in possession, care should be taken that they are not smothered by any vigorous subjects which may be growing near them.

A Good Winter-Flowering Shrub.—The value of *Pieris floribunda* or *Andromeda floribunda* as a hardy winter-flowering shrub does not appear to be generally appreciated. It may be due to the fact that it is rather a slow grower, although in a small state it is very ornamental. It commences flowering now, and often continues till February or March; but sprays open freely in water and keep fresh for several weeks. Like most other North American shrubs, it likes peat, but will thrive in soil suitable for *Rhododendrons*, and when planted should be made firm.

A Beautiful Winter Heath.—Although *Erica carnea* is often spoken of as the Winter Heath, it does not usually reveal the full beauty of its flowers until February is here. Much earlier and quite hardy is *E. mediterranea hybrida*. This we have flowering now in a position facing north and in ordinary well-drained soil, to which neither peat nor leaf-soil has been added. Its flowers are of a charming rose pink colour, and it makes a neat tuft of growth about nine inches high, exceeding this a few inches with age. This winter-flowering Heath deserves to be much better known than it is at present.

Pruning Evergreens.—There are a number of evergreen shrubs that require a certain amount of pruning to keep them in a symmetrical shape. Advantage may be taken of this time of the year, as there is always a demand for such material for decoration, and the one operation serves the two purposes, as such material keeps fresh for a long time if placed in a cool position. Unless the shrubs are intended to form a hedge, cutting back to a flat surface is to be avoided. It is much better to remove the projecting branches by cutting them right out, rather than form a wall-like appearance as we often see.

Rose Gloire de Dijon.—Some beautiful blooms of this old Tea Rose gathered from the open garden on Sunday last, the 7th inst., reminded us that this is usually the earliest of the double Roses to flower and the last to finish. Often we have had good blooms before May had departed, and we have yet to find a new Rose that will, even in a season such as this, give us flowers during eight months of the year. Although raised so long ago as 1850, we are glad to find that the sterling qualities of *Gloire de Dijon* are still recognised. It is a good climber and very sweetly Tea-scented; hence we can well afford to overlook the fact that some of the flowers come with divided centres.

Perpetual-Flowering Carnations.—These charming flowers of winter bid fair to become almost as popular at this season as the Rose is during the summer months. The splendid exhibition held by the Perpetual Flowering Carnation Society in London last week, and a report of which appears on another page, served to draw attention to the usefulness and the charm of these flowers. Some of the dinner-table decorations were very good indeed, especially under artificial light, a test that many so-called dinner-table decorations do not emerge from successfully. It was gratifying to note that the public attended well, and thus showed their appreciation of the work the committee is doing.

A Useful Berried Shrub.—One of the brightest shrubs just now is *Cotoneaster Simonsii*. It has nothing to its discredit except that it is by no means rare. If it were difficult to obtain or grow, it would be at once placed in the front rank of shrubs for winter effect. This *Cotoneaster* will thrive in almost any soil or situation, is particularly good for towns, and rarely fails to produce a heavy crop of its bright orange-coloured berries, which hang on the branches sometimes as late as May and retain their colour the whole time. It grows fairly rapidly, but can be kept in bounds by occasionally shortening back those growths that are too venturesome.

"The Garden" in 1914.—We hope next week to be in a position to make an announcement that should be of considerable interest to our ever-increasing number of readers. We have been able to secure an unparalleled list of authors and articles for the coming year, some of which we hope to announce in our next issue. The reputation for authoritative articles and artistic illustrations which THE GARDEN has enjoyed ever since its foundation over forty years ago has increased year by year, and no effort will be spared to keep this reputation. The contributions which have been already promised for 1914 enable us to look forward with no small degree of confidence to a brilliant New Year. We take this opportunity of expressing our warmest thanks to a very large number of correspondents who have written to us acknowledging their indebtedness to and cordial appreciation of THE GARDEN.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Some Good Chrysanthemums.—I have pleasure in sending you a photograph of a group of our 1913 exhibition Chrysanthemums. These plants were rooted in the months of January and February in a cold greenhouse, and proved very successful throughout the whole season, being free from rust and maggot, and retaining their foliage from the rim of the pot upwards to the flower in a splendid condition. You will notice that the blooms are a fine size, but the largest flowers were those of F. S. Vallis, R. Vallis and F. Payne. —A. E. LUTTMAN, *The Gardens, Crookley Park, Horndean, Hants.*

A Little-Known Rose.—Referring to the question of a little-known Rose called Donarte de Elvira, mentioned in your "Correspondence" column on page 595 of November 29 issue, I find, both in Pernet-Ducher's and Ketten's catalogue, what, by the description, is evidently the same

been in Portugal that it is a great favourite in Portuguese gardens. It came to me many years ago among some Roses from France, and I was so delighted with it that I ordered it again and again, both for myself and for many of my friends who admitted it. It is a Noisette, and here in North Notts it does better on a wall than climbing over poles. It grows very quickly, and is constantly covered with flowers of a beautiful shade of salmon pink. Everyone who sees it admires it and wants to know its name. I think it such a pity that so few English nurserymen grow it. —AGNES MELLISH, *Hodsock Priory, Notts.*

Canary Seed as a Christmas Decoration.—I think some of your readers may not know the very fresh and dainty Christmas "greenery" that can be obtained by sowing canary seed now. I always sow it about three weeks before Christmas Day in small bowls and vases not more than 4 inches to 6 inches deep. I fill these with coarse sand to about an inch below their rims, soak them thoroughly, and sprinkle evenly a layer of canary seed on the surface; then put them in a warm, dark place, keeping them daily moistened

and the plant measuring 21 inches through, naturally one would say, "I wonder how much they measure across"; hence my meaning 6 inches from tip to tip. But as for growing old corns, I do not think I shall ever do that, because I have never seen the blooms of old corns come up to those blooming the first time, and we are quite satisfied with seedlings here. I have measured several of our plants, and find some are 22 inches and the majority 18 inches through. Of course, they have not yet finished developing. I counted the leaves on one plant, and found it was carrying 115, the largest of them measuring 4 inches in diameter. So all the time we get those results, no old corns for us.—F. C. WILLIE, *The Gardens, Great Walshead, Lindfield, Sussex.*

Rosemary and Carnations.—Noticing your remarks about foliage for associating with cut flowers, especially of a light nature, on page 581 of November 22 issue, I might say that Rosemary is an ideal plant in the Sunny South, but in northern climes this cannot be depended on. This year a trial was given to an annual under the name of *Artemisia sacrorum viridis* [*Artemisia annua*.—Ed.] Seeds were sown in April, and by August the plants had developed into fine Cypress-like bushes in the open borders, and have since, almost daily, yielded quantities of foliage. This is scented, is very light, and mixes well with almost any flowers, hardy or tender, although it ought never to be associated with flowers that are fragrant, otherwise their natural fragrance is apt to be somewhat lost. This plant does not seem to be in the Kew lists. Is it known under another name? It is a plant that ought to be widely known and widely grown. Eucalyptus, especially *E. globulus*, grown in the open during the summer, is also a welcome foliage plant suitable for cutting and arranging with cut flowers, as also are the long, leathery growths from *Lupinus arboreus*. There is yet another subject that is oftentimes forgotten, viz., Lemon-scented Verbena (*Lippia*). This, raised from cuttings early and planted out in a warm border, provides a lot of fragrant foliage, at this season.—H. R., *Twicken, Holland.*

Plants Flowering Late in Yorkshire.—Much has been written to the papers about plants in bloom so late in the year. How about the following, now in bloom in my garden in this north-east corner of Yorkshire, eight or nine miles from the sea and 300 feet above it? Geums, Violas, Roses in quantity, *Chrysanthemum maximum* Wynward, *Berberis Darwinii*, *B. Aquifolium*, *Arabis flore pleno*, *Doronicum*, *Veronica repens*, *V. Bidwillii*, *Aubrietia*, *Arabis Billardieri rosea*, *Achillea umbellata*, *Lithospermum prostrata*, *Linum perenne*, *Andromeda floribunda*, *Arbutus Unedo*, *Viburnum Tinus*, *Alyssum saxatile flore pleno*, single *Alyssum*, Sweet *Alyssum*, *Ionopsisidium*, *Campanula muralis*, *C. persicifolia*, *Potentilla aurea*, *Anneria lauchiana*, *Dianthus atrorubens*, *D. graniticus*, *Primula capitata*, *Sedum spurium*, *Gaultheria procumbens*, *Polygala Chamæbuxus*, *Phlox verna*, *Santolma Chamæparissus*, *Gentiana acaulis*, *Antheus Aizoon*, *Acena microphylla*, *Cyclamen neapolitanum*, *Hutchensia alpina*, *Primula cashmeriana*, *Anthrinum*, *Primula Double White*, *Helianthemum*, perennial Sweet Pea, *Erigeron mucronata*, *Meconopsis cambrica flore pleno*, *Clematis Mrs. Moser*, *Jasminum nudiflorum*, *Iberis sempervirens*, *Hieracium aurantiacum*, *Cerastium Bieberstemii*, early-flowering Chrysanthemums, *Ericas* in several varieties, *Pernettyas*, Bunch Primroses by thousands, Pears and Strawberries. J. J. BURTON.

EXHIBITION CHRYSANTHEMUMS AT THE GARDENS, CROOKLEY PARK, HORNDEAN, HANTS.

Rose, but named Duarte de Oliveira (Brassac, 1880). It is described as a very vigorous climber, floriferous and of coppery salmon rose.—CHARLES B. BRAGG, *Handsworth, Birmingham.*

—I was pleased to see a note upon a variety your correspondent calls Donarte de Elvira (page 595). It is a great favourite of mine, but lost to me just at present. I believe the correct name is Duarte de Oliveira, and it was sent out by M. Brassac in 1880 or 1881. It is given as a cross between Ophirie and Réve d'Or, and those who know these two varieties can form a good idea of it when I say it partakes of both parents about equally. It is strange how some of our useful old Roses get missed; and yet at that time of day M. Brassac was well known as one of our best French raisers.—A. P.

—I am delighted to see that your correspondent in THE GARDEN of November 29 is writing in praise of a little-known Rose that is a great favourite of mine; only may I venture to correct her in the spelling of the name, which should be Duarte de Oliveira. I supposed it to be Spanish, but was told by a friend who had

with tepid water till the little pink tops are about an inch high. Then I bring them to a sunny window, and, turning them round daily (so that they grow up evenly), I have the pleasure of watching their rapid progress to clusters of bright pink and green foliage. When grown, they last another three or four weeks in good decorative condition, even in rooms lighted by gas. By that time I have another batch (sown at the close of the year) to take their place. Sometimes I stick some early-cut Snowdrops among them, with good effect. Their bright, fresh, verdant hue is very pleasing to the eye in the dark winter days.—ANNE AMATEUR.

Measuring Cyclamen Flowers.—In reply to Mr. Blair re the measuring of a Cyclamen flower, page 594, issue November 29, I measured it by stretching the bloom flat. Perhaps it would have been more explicit had I said each petal measured 3 inches; but I was tempted to measure them that way, and under the circumstances I think most people would have done so; for, take a plant carrying seventy-one fully-expanded blooms, some of them with six and seven petals,

WHICH IS THE GUERNSEY LILY?

I MEAN the *old original*—the variety that has given rise to all the myths and tales that are told to account for the introduction of this Japan (?)—Cape of Good Hope bulb into the little island of Guernsey, where, as we say in my part of the world, it at once made itself at home and grew away "like squitch."

Whether it is Banbury cakes, or Shrewsbury cakes, or Everton toffee, or the Guernsey Lily, there is a sort of historical satisfaction in being quite certain which is the "old original." It adds a something that nothing else can. Which, then, of all the many *Nerines* is the true Guernsey Lily? I used to think it was *N. sarniensis*, and that *N. sarniensis* was in colour a sort of pale orange red. In Nicholson's Dictionary it is said to be "pale salmon coloured." This summer I bought some of what was said to be "the real thing" from the island itself, and the other week, when I paid a visit to Colesborne to see Mr. Elwes, and his magnificent collection, I took him a flower of my new purchase, which he at once pronounced to be "rosea." Since my return home I have gone further into the matter, and I have turned up the *Botanical Magazine*, where, on Plate 204, the Guernsey Lily, or, as it was then called, the *Amarallis sarniensis*, is pictured. There it is undoubtedly rose-coloured, and in the explanatory text the description of Dr. Douglass (*sic*) is quoted: "each flower in its prime looks like a gold tissue wrought on a rose-coloured ground." About a year ago a copy of Dr. James Douglas's "Monograph on the Guernsey Lilly" came into my possession, and so I am able to verify this allusion in the *Botanical Magazine*, and also to add the interesting information that the author claims to have given the name *N. sarniensis*. He says on page 8 of the enlarged second edition of 1720: "To this island likewise we owe its common English name, the *Guernsey Lilly*, which I have ventured to render *Lilium Sarniense*, on the authority of the Learned *Cambden*, who tells us, that *Sarnia* is the Latin name used by *Antoninus* in his *Itinerarium Maritimum* to express the island of *Guernsey*." (The italics are in the original.) As Dr. Douglas gives a chronological list of names from 1035 to 1720, and the title *N. sarniense* does not appear, I presume his statement is correct. If so, then the true Guernsey Lily is rose-coloured.

If there was nothing more to be said, I would consider the question as settled, but it is not so. There seems to be the possibility of a second "old original" having come to the island *via* Paris, if the "Narcisse de Japon" of P. Morin was a true *Nerine* ("Remarques necessaires pour la Culture des Fleurs," edition 1667, page 24). Or if John Rea is to be trusted ("Flora, seu de Florum Cultura," 1665, page 78), there seem to have been, even in those early days, more varieties than were known, except by hearsay in England.

Hence it seems to me that even then (*c.* 1660-70) the Guernsey people may have had not only *sarniensis rosea*, but also *corusca* and something akin to *undulata*, and that the name Guernsey Lily was from the first not so much specific as generic. Is there, then, any *one* "old original"? JOSEPH JACOB.

December 18.—Linnean Society's Meeting.

THE ROSE GARDEN.

ROSE-GROWING IN TOWN GARDENS.—II.

IF the Rose were as easily cultivated as the Marigold, half the enjoyment of growing it would be gone, and certainly we should not all appreciate it as we do now. Fortunately, then—or unfortunately if you prefer it—the Rose is more subject to the attacks of insects and suffers from a greater variety of complaints than any other flower of our gardens, and in this respect the town-dweller is especially favoured. He cannot escape these pests entirely; but, by observing a few simple rules at the commencement, he can prevent them from getting the upper hand, and so lessen the amount of work entailed subsequently. I have already pointed out the advantage of having the beds as far as possible in the open, away from walls or fences. The neighbourhood of trees must also be avoided. Sunshine and air mean health and strength, and strong plants are better able to resist disease. Another important point is that the beds should not be made too wide. Three feet is a convenient width, which will just accommodate a double row of trees and leave room for a narrow border of *Violas* or some other edging. So planted they are more easily accessible, and can be better looked after than where the bed is a wider one.

In towns especially we must avoid those varieties with weak constitutions, or which are especially subject to mildew. Nor is it of any use to nurse sick plants. It is better at once to get rid of them and fill their places with healthy trees which will start fairly. Old and worn-out specimens that have not bloomed satisfactorily are also best got rid of. Usually these have exhausted the food in the immediate neighbourhood of their roots, which have penetrated deeply into unprepared soil and are practically out of reach of fertilisers. Do not yield to the temptation to carpet the beds with other flowers. Remember, the continual use of the hoe throughout the growing season is quite as important as manure. Lastly, give ample room between the plants.

The greatest handicap of the town gardener is smoke. Frequently it is present in the atmosphere to such an extent that in dry weather the leaves become coated with a layer of grime. Now every leaf has many thousands of tiny holes in it, called stomata, and through them the plant absorbs the necessary gases and discharges superfluous moisture, just as we do through the pores of our skins. It will be seen, then, how important it is that the leaves should be kept clean. This is one reason for using the syringe freely and frequently.

Of insect pests, the aphid easily takes first place, both by reason of its ubiquity and in point of numbers. It has been calculated that the great-grandchildren of one aphid might number over sixty millions if all could find standing room and were left unchecked. Fortunately, the death rate is high; but it is hard work to keep it uniformly at 100 per cent. in our own gardens and to deal with alien immigrants as well. Steel the heart and soil the fingers. It may be a messy job, but is a very effective way of keeping them down. One quickly becomes expert at running over a growth with finger and thumb, and, if this be done regularly, a great many trees can be looked over in a few minutes; but the hand must always be supplemented by the syringe. While we are looking for aphids we shall, of course, catch caterpillars, and here hand-picking is by far the most

effective remedy. Whenever a leaf is seen to be curled or eaten, go carefully over the whole tree. Moths never lay their eggs singly. One of the most harmful of larvae is that of the sawfly, which does considerable damage to standard Roses by boring into the pith. To prevent this, the cut parts should be painted over with enamel when the trees are pruned. Cuckoo spit is often troublesome in towns, and the little green insect must be caught and slain before he has time to blow bubbles with more of the precious sap. Earwigs must be looked for in the blooms. These are all the insects the grower need worry about. Ants will not trouble him if his beds are hoed regularly.

The worst enemy of the town gardener is mildew. This usually makes its appearance towards the end of July, but long before then one must take active measures to combat it. It is best, therefore, when spraying, to use a preparation that is equally effective for dealing with mildew as well as aphids, and there are many excellent combined insecticides and fungicides. If expense be a consideration, a very cheap, easily-made and effective remedy may be made up as follows: First make a strong stock solution by dissolving Lifelav Soap in boiling water. To two gallons of water add an ounce of liver of sulphur, previously dissolved in a pint of hot water, and as much of the soap solution as will make it lather freely when stirred. The quantity will depend on whether the water be hard or soft, but the latter should always be used for preference, rain-water if procurable. Spray the under sides as well as the tops of the leaves, and syringe with clear water about two hours afterwards.

Black spot, fortunately, is as fond of country as of town life. Regular spraying with liver of sulphur will prevent its appearance. Where a plant is infected, it is best to burn it at once, rather than run the risk of the disease spreading. My next article will deal with some of the Roses best suited for town culture.

P. L. GODDARD.

(To be continued.)

IN A HAMPSHIRE GARDEN.

SOME OF THE NEWER DECORATIVE VARIETIES.

(Continued from page 615.)

Irish Fireflame (Hybrid Tea, Alex. Dickson and Sons, 1913).—I have very little to add to the notes that I have contributed on more than one occasion to your columns concerning this Rose, except to say that the result of growing Irish Fireflame for the past season has only been to add to my admiration of this very beautiful Rose. It is still producing buds and flowers; but, of course, the brilliance of the colouring of the normal flower is lacking somewhat in these December blooms. It proves, however, that the ground colour is yellow, and not pink as in Irish Elegance. I confidently expect to pick flowers of this variety (if Jack Frost does not intervene) at Christmas. No lover of single Roses should be without a plant of Irish Fireflame, the most beautiful of all singles.

Lady Dunleath (Alex. Dickson and Sons, 1913).—I made an especial note of this variety last year at Newtownards, and I am glad that Messrs. Dickson have been able to put it into commerce this year. It is a lovely Rose, with all the refinement of a pure Tea, coupled with the vigour and shape of a Betty, only fuller, with more petals. To call it a yellow Betty hardly does it justice, for it has, I think, more shape and substance. Outside of the petals creamy white, with a deep yellow centre. It is a delightful Rose. The plants carried plenty of bloom, and it is bound to

A PARTIALLY-SHADED BANK CLOTHED WITH ST. DABEOC'S HEATH
(DABŒCIA POLIFOLIA).

become very popular, especially with the ladies. It is fragrant.

Lady Greenall (Alex. Dickson and Sons, 1911).—The note of distinction about this Rose is very marked. Its exquisite shape accounts partly for it, perhaps, but it is the *tout ensemble* that is so pleasing. "Like a queen's her golden head" is a line that always occurs to me in connection with this Rose. It is a good grower, the flowers held very erect on stiff, long stalks, with a strong Tea perfume. With me almost, if not quite, free from mildew. Colour not unlike the last named—that is, white or cream—with yellow or gold in the centre of the flower.

Lady Hillingdon (Tea, Lowe and Shawyer and G. Mount, 1910).—Undoubtedly the best bedding Rose of its colour, namely, a good, sound golden orange and deep apricot. Very free-flowering, free from mildew, a good grower, but the flowers are not held quite upright. It makes an excellent standard, a most beautiful bed, and one of the best of button-holes. Now that it is down to normal prices it should be in every garden. Those who want it should order it at once, as the stock is very nearly sold out for this season, so I am told.

Lady Margaret Boscawen (Alex. Dickson and Sons, 1911).—Another very pretty button-hole, both in the half-open bud and fully-expanded flower, as the latter is not too large. It is a soft pale flesh colour, very delicate and pretty, a good grower and opener, with a delicious scent

of these new Roses that strike a distinct note do) from over-production, and it was not too vigorous to start with; in fact, one would almost have called it a poor grower. But now that it has had time to get established, it is quite a different matter, and it makes an ideal bedding Rose. The varying colours of its petals are delightful, and there are few more beautiful Roses for table decoration. Salmon overlaid with a deep copper red, mixed with fawn and yellow; they are all there at different stages. The flowers are medium size and not very full, but they open well in all weathers, and stand the rain a great deal better than most Roses.

Leslie Holland (Hugh Dickson, 1911).—This makes a fine bedding Rose. The colour is very fine in the young flowers.

Little Dorrit (Tea, Paul and Son, 1912).—A very pretty China Tea of good growth. Buff and carmine tinted—a pretty combination.

Mme. H. de la Valette (China, Schwartz, 1910).—This is another China of even deeper colouring than that old favourite Mme. Eugène Resal, yellow, shaded coppery red of the brightest shades. A good grower and very free. Can be recommended.

Mme. Jules Bouche (Cromber et Fils, 1911).—This is a pretty Rose of a refined Maiden's Blush colouring, very free, of good habit, and the flowers of quite good shape.

Mary Countess of Ilchester (Alex. Dickson and Sons, 1909).—A very free-flowering, vigorous,

Lady Mary Ward (S. McGredy and Son, 1913).—This is a wonderful piece of colouring very difficult to describe, burnished copper and deep orange, almost a bronze shade. A very fine bowl of it attracted a great deal of attention at the National Rose Society's Autumn Show. The flower is of good shape for a decorative variety, and the plants can be placed somewhat closer together than is usual, as it is not a vigorous grower. Lady Roberts was once described by a Rose-loving parson as "William Allen Richardson gone to heaven"! Lady Mary Ward might be described as Lady Roberts gone to the same place. It is quite unique in its colour-scheme.

Lady Pirrie (Hugh Dickson, 1910).—This Rose has improved very much with me this year, both in colour and growth, so much so that one can fairly call the latter vigorous. No doubt it suffered (as so many

growing bedding Rose of bright carmine colouring in the younger flowers and buds, shading to a crimson carmine in the larger, fully-open flowers. Fragrant and nearly free from mildew.

Margaret Molyneux (Alex. Dickson and Sons, 1909).—Named after my eldest daughter. A beautiful decorative Rose that flowers in large trusses on long footstalks right up till the frost. Deep saffron yellow in the bud, fading to a bright but pale cream in the open flower. A Rose of few petals, but delightful if cut young and used for the house. Sweet-scented and a good grower.

Melody (Alex. Dickson and Sons, 1911).—A Hybrid Tea with a lot of Tea blood in its veins. A beautiful Rose with a somewhat curious name. I suppose the idea is all right—"If only I could speak, what a song I could sing." My plant has pleased me so much that I am making a small bed of it, and there are not many Roses that I can promote to that distinction in my small garden. A real good yellow, of a lovely Tea shape, deep primrose shade in colour, fine growth and mildew-proof. A table of this Rose at the National Rose Society's show in the autumn won first prize.

Moonlight (Rev. J. H. Pemberton, 1913).—This is an entirely charming Rose, judging from the numerous exhibits staged by the raiser, and well worthy of the gold medal of the National Rose Society, which it obtained at the Autumn Show this year. It is described as a semi-climber, obviously a seedling from Trier or from the same strain. I noticed one of your contributors seemed to think the National Rose Society was making a great mistake in giving such a Rose a gold medal. Why, I wonder? The National Rose Society is out to encourage all kinds of Roses, not exhibition varieties only. A Rose that can give us its flowers in such profusion and of such good quality in the autumn as Moonlight does is very welcome, and its raiser should certainly be encouraged to go on and give us something more, even better if possible. If he does, I am sure other gold medals will be his reward.

THE HEATH GARDEN.

A BANK OF ST. DABEOC'S HEATH.

IN order that hardy Heaths should be seen to their best advantage, it is necessary that they should be planted in a semi-wild place where they may assume their natural beauty. To grow Heaths in circular or angular beds is to deprive them of half their charm. Most of the Heaths will succeed under the partial shade of trees, where they should be allowed to spread more or less unchecked in all directions. St. Dabeoc's Heath is one of the most desirable of them all. It is not an Erica, although it is closely related to that genus, but is known botanically as *Dabœcia polifolia* and *Menziesia politola*. Like most other Heaths, it thrives in a sandy peat soil to which a fair quantity of loam is added. It is well suited for planting on the fringe of a shrubbery or woodland, while for growing over rockwork or for clothing a bank it has few equals. Our illustration depicts a bank clothed with St. Dabeoc's Heath in Messrs. James Box's rock garden at Lindfield, Sussex. Here the white, rose and purple forms of this Heath grow so freely that they have to be kept within bounds, while in the long season from early June till late September the flowers are freely produced.

ROCK AND WATER GARDEN.

THE DESIGNING, CONSTRUCTION AND PLANTING OF ROCK GARDENS.

(Continued from page 608.)

Selection of Stone.— This is frequently a matter of the locality in which the work is being carried out, and is controlled by the matter of cost, as it is hardly probable (and rarely advisable) that one would import a foreign stone into a district abounding with natural rock of any sort. Opinions differ very greatly as to the best stone to use, and I think it depends to a very great extent on the point of view from which you approach the question; certainly, much on the class of work for which it is to be used.

We had a fine collection of samples to study during the Royal International Show at Chelsea, 1912, and the Royal Horticultural Society's Spring Show, 1913, and a careful comparison leads me to place them in the following order of merit: The winner of the first prize in the 600-leaf class at the 1912 show and a gold medal at the 1913 show (Mr. Wood) used a grey limestone, collected in beautiful weather-worn pieces in a certain district in Yorkshire. The advantages of this stone are so obvious that it seems unnecessary to recount them. Especially is it suitable for small rock gardens; indeed, it is hardly suitable for bold or extensive work, as it is difficult to obtain anything in the nature of large pieces. The cool grey colour, porous nature and weathered appearance all combine to make this stone one of the most attractive, both as regards appearance and for plant culture. The grey limestones used in the exhibits of Messrs. R. Wallace and Co., and Mr. Clarence Elliott in the 1913 show, are in many respects so similar that they are certainly worthy of mention in association. Moreover, they are both obtainable in large pieces, and therefore more suitable for bold work. Next in order I placed the oolitic limestone from the Purbeck Hills, used in two of the larger of the "trade" or non-competitive exhibits at the International Show, 1912. I do not think there exists anything more beautiful for rock gardens when in association with water than this stone. It is an easy stone to use, as one can scarcely make the mistake of placing it in any but the right position. It never looks new, and, so long as it is used the right way up, *never* seems to be asking itself how it comes to be in its present position. Even when the inevitable disaster occurs, and a few pieces of it get left lying quite bare, through the death of the plants surrounding them, it is sufficiently picturesque in itself to be quite unobtrusive, which is more than one can say of many other stones. It can be obtained in pieces of considerable size, and so used for large or small rock gardens. The next three stones run each other very closely on points, although each has its distinct advantages. One is the well-known Bargate stone, excellent for effect and plant-life, but very difficult to obtain in pieces sufficiently large for really effective work; another, Derbyshire sandstone or grit, that can be abnormally ugly unless carefully used (which it rarely is). To all appearance this stone is too hard for rock plants to thrive thereon, or even vegetate, but experience has taught us that they will succeed admirably on or among it. It is obtainable in any-sized pieces required, up to eight-ton blocks. For big, bold work it is invaluable, and very cheap. Many notable rock gardens have been constructed with it, particularly, I might mention, that at Friar Park, Holey, and (I believe) also that at Warley Place,

Against Sussex sandstone I have two objections. The colour when new is very distasteful, and even when weathered it is likely to fritter away in parts and leave ugly yellowish patches glaringly exposed. In every other way it is an excellent stone; plants love it. Care must be taken in using it that it does not become rigidly "beddy" in appearance. It usually comes out in thick, flat slabs that must be used flat, and the consequence is that it sometimes becomes monotonous in outline. There is also a good Yorkshire sandstone closely allied to the Derby grit previously mentioned, that is very useful for bold, massive work, but it is not the most desirable stone in association with water. Of all the stones used in the International Show, I liked the Kentish ragstone the least. Cold, hard, undesirable in colour, its only advantage seems to be that it is a cheap stone to use at home. It should never be sent far away. There are, however, some grades of this stone much more suitable than others. There are other fine stones, notably on the Western borders of Oxford, in parts of Gloucestershire, and many others; but the range I have given will serve for the purpose of comparison.

Where the intention is to utilise a suitable site for the introduction of picturesque *rock* effects, the principal requisite is stone of bold, rugged formation that is sufficiently susceptible to climatic and atmospheric action that it will take on a weathered appearance quickly, and yet is not affected to any great extent by frost. If, however, the intention is to cultivate alpines, a softer stone is desirable, and a slight frittering away of particles is really desirable for many plants. Needless to say, as so many alpines revel in limestone, this is the most serviceable. Indeed, there is a limited number of plants that will not thrive without it.

GEORGE DILLISTONE.

Colchester

(To be continued.)

CORYDALIS THALICTRIFOLIA.

WHEN this plant was shown for the first time in this country some ten or twelve years ago, it was welcomed as a very promising subject for the cool greenhouse. Since that time, however, it has proved its worth in the open rock garden, for it planted out in the spring in a favoured nook it quickly

establishes itself and can be relied upon to throw up its bright yellow spikes of flower in good numbers. Moreover, the foliage of this plant is very decorative, and it never looks better than when draping boulders of rock, particularly if the leaves have assumed that bronze tint peculiar to this species. As a greenhouse subject this *Corydalis* is of great value, both for pots and baskets. Its seeds freely, and the seeds germinate readily under glass if sown quite early in the year.

A BEAUTIFUL PRICKLY THRIFT.

(*ACANTHOLIMON VENUSTUM*.)

THIS is one of the most attractive of the Prickly Thrifts, much more refined in appearance than its more ordinary relative, *Acantholimon plumaceum*. The foliage is narrow, somewhat resembling that of a *Dianthus*, and when the new leaves first form they are quite soft and flexible. As they mature, however, they become intensely rigid and spiny, and are as sharp as a needle at their points. The colour of a tuft of this plant is a soft greenish grey, tending more to grey as the plant increases in health. The flowers, which

CORYDALIS THALICTRIFOLIA FILLING A SHELTERED NOOK IN THE ROCK GARDEN.

are of a bright rose tint, are produced in July, a point of considerable value when so many of our choice alpine plants are early flowering.

The arching spray of buds is curiously suggestive of a grass plume, while the cinnamon-coloured calyx, which finally develops into a saucer-shaped frill, persists for some time after the flowers have fallen. Here at Woodford it thrives in a gritty compost to which old mortar has been liberally added, in a position fully exposed to the sun, and protected from winter wet by a roof glass. Last year in M. Dallenges' garden at Chêne-Bourg, Geneva, I saw several magnificent tufts—by far the finest I have ever seen—reveling in the torrid sun-bine of that district and aglow with numerous sprays of flowers.

The propagation of this plant is difficult, since it roots very deeply, with almost fibreless thongs. It is said to "layer" if outstanding pieces are pegged down and fine soil placed upon them,

THE GREENHOUSE.

SEASONABLE NOTES ON CARNATIONS.

THE Editor requests me to send a few notes from time to time on the fascinating subject of Carnations, and as a preface I wish to ask readers to peruse these notes as being tempered with the exigencies of a Scottish climate at least as difficult as that of the Midlands. At this time of year Perpetuals are by far the most interesting section, and from which we are reaping the fruits of a prolonged and exacting attention, while many of us are preparing for the harvest of another winter.

At the time of writing, the bulk of my own cuttings are rooted. Propagation begins early in October, the cuttings receiving stove treatment. Roots are emitted in a week in the case of

have been topped, the hard, cold treatment being just the thing to enable them to break strongly and freely. The other stages of the structure in which are the young plants contain the choicest of the flowering stock, the remainder occupying a much larger structure along with *Chrysanthemums*. These are freely ventilated unless the weather is unsuitable, and a slight heat in the pipes by night and by day secures a buoyant and dry atmosphere, the two chief requirements to hinder the development of leaf-disease, and they also enable the plants to keep on the move, though slowly, and the forward buds to expand in a kindly manner. For the next six weeks—the most trying in the Carnation cycle—manure, if applied at all, must be meted out with great judgment. Nitrogenous manures especially, which if estimated by the appearance of the foliage might be concluded to be valuable, should *not* be used, a flaccid condition of the flowers, accompanied by a weak calyx that more often than not splits, being results which follow their use. Another cause of weakness in some varieties is the production of too many growths, which if left without reduction either do not flower or only yield small blooms. Lady Alington, May Day, Mikado, Britannia and Mrs. F. Burnett are varieties which transgress in this way, and these should be examined and thinned two or three times in the period from October to May. Those left in a very short time increase in vigour. This is a little cultural expedient which is easily overlooked, but it is a very important one where only one set of plants is grown to provide an uninterrupted supply of flowers. In cold weather lower the temperature to 45°.

Malmansons must be kept as quiet as possible until the turn of the year, the season's layers being kept rather drier at the root than two year old plants. When the latter are allowed to become and remain dry for too long a time at the roots, the old foliage gets desiccated, turns yellow, and the plants on the whole are much the worse for the experience. It is just the distinction between not overdrying the plants and giving a little too much water that the enthusiastic grower has to observe. Standing in the same structure with Perpetuals, the warmest part and the least ventilated should be given up to Malmansons. Both sections need to be vaporised at frequent intervals as a preventive measure against aphid infestation. Borders established in outdoor beds may require weeding after the unusually fine weather. The spade is an efficient implement for the purpose at this time of the year. The method to follow consists in pushing the spade along about two inches under the soil surface, transposing each spadeful so that all the little weeds are buried deep enough to destroy their vegetative powers, and at the same time leaving a surface of clean, fresh soil. Stock being wintered in frames should be ventilated always. The severest frost does not harm the plants, but a stagnant, damp atmosphere does. Care should be taken that the pots are covered over the rims to secure them from breakage.

Tyringhame

R. P. BROTHURSTON.

ACANTHOLIMON VENUSTUM, A USEFUL PRICKLY THRIEFT FOR THE ROCK GARDEN.

aided by a piece of stone to retain the moisture in the soil, though so far I have not tried this plan. My own plants originated from root cuttings about ten inches long, which, after being firmly planted in the above-mentioned compost, were tended carefully for some three or four weeks and have now made quite a nice colony. It is said to come well from cuttings when the necessary skill has been attained, while seed, when it can be procured, is doubtless the best means of securing strong plants. It is said to suffer during severe cold, and it caught by a cold snap while lying wet may be killed outright. Probably the roof glass already mentioned, coupled with perfect drainage, will minimise any untoward accident of this kind, at least in these more southern counties. It is a subject worthy of all the care that one may bestow upon it.

R. A. MALBY.

quick-rooting varieties, and generally they are ready to be potted in a fortnight. The cuttings being so brief a time in the propagating-house, the soft growth prophesied by some folks as a result is never apparent. I am fortunate in having pits just suited to the simple requirements of the little things. For standing them on a stone stage, which keeps them cool at the root and near enough to the glass to negative etiolation, is an item of first-rate importance. The ventilation is of a kind that on fine days air can be admitted to play all around them, or on cold ones and during high winds shut off altogether. I know that in spring many growers bring on young stuff in rather warmer and less well-ventilated structures, but during the winter such treatment would inevitably ruin the plants. By the time this is printed the best-rooted plants, which are those which have rooted round the balls, all in 4-inch pots, will

SINGLE AND DECORATIVE CHRYSANTHEMUMS.

THERE is a demure charm and beauty associated with Chrysanthemums, for they contribute largely to our pleasure and enjoyment in brightening our homes and gardens at one of the duller periods of the year.

The cultivation of decorative and single Chrysanthemums does not materially differ from that generally given the other sections of this family. They may with advantage be propagated later, splendid plants being obtained by propagating in March. A fruitful source of failure is propagating too early and starving the plants before they reach their flowering pots. Propagated at the date named and grown coolly, giving successive shifts as the pots become well filled with roots, and employing loam of good quality, success is readily assured. The soil for the final potting is the most important, and should consist of four parts good fibrous loam, with a third part each of leaf-soil, sand and horse-manure, and a 4-inch potful of soot, bone-meal and an approved fertiliser, such as Thomson's, Clay's or Bentley's, to a well-heaped barrow-load of soil. The compost should be thoroughly mixed and used in a condition that admits of firm potting, and, except in the case of specimen plants, pots having an internal diameter of $7\frac{1}{2}$ inches to 8 inches are quite large enough.

The Best Singles.—One of the earliest singles to open is Joan Edwards, a variety with stiff, erect stems, and flowers of a good rose shade. Mary Richardson follows immediately with reddish-salmon flowers of a most attractive shade that is particularly effective under artificial light. This shade is practically repeated in Lady Furness, a variety that flowers in December, and this season the plants promise to be exceptionally good. All the Pagram family produce good decorative single flowers. These include Edith Pagram, rich pink, with white zone; Mrs. Tresham Gilbey, pure yellow; and Bronze Pagram, reddish bronze and yellow. Mrs. W. Garner is an improved and larger form of the latter, while White Pagram gives pure white flowers. Sylvia Slade is a particularly showy flower of rose-garnet colour, with an inner ring of white, after the manner of a Cineraria. Ethel Ashdown is similar to this, but on a much larger scale. One of the loveliest white flowers is found in Mensa. These are equally good disbudded or in natural sprays. Other good whites include Mrs. P. Sterling, Stella, Mrs. C. E. Abbott, Robert Thorpe and Gertrude. Florrie King forms beautiful flowers of pale flesh pink. Gracie Trower is lavender pink, and Gracie Lambert a deeper shade of pink. Among chestnut shades, Leo, Mrs. W. G. Patching, Oriental and Walton are particularly good. This colour is effective as a luncheon-table decoration, and is equally good under artificial

light. Of dark shades, Arcturus, C. J. Ellis, Sandown Kadance, Belle of Weybridge, Roupell Beauty, Hale Crimson and Camell's Crimson are all effective colours, and cover a season extending from October till January. Good yellows include Queenie Jessop, Kitty Bourne, Marchioness of Cholmondeley, Norah Bramwell, Sharston and Golden Mensa.

Of Double Varieties that develop good flowers when grown in natural sprays, the Caprice family are indispensable, coming into flower in succession to the outdoor kinds. Kathleen Thomson is one of the brightest, coloured chestnut crimson, with gold tips; Caprice du Printemps, bright rose pink; and

flower. Crimson Quintus gives particularly graceful and light sprays of glowing crimson shade. Mrs. C. Beckett gives white flowers that are tinted green in the early stages. Mrs. J. H. Silsbury and Godfrey's King provide beautiful decorative flowers when grown in bush form and the laterals disbudded to a single bud. For mid-December flowering Baldoek's Crimson is invaluable, with flowers of a bright reddish crimson. Matthew Hodgson, rich crimson; Framfield Pink, rich rose; Christmas Rose, fine shade of pink, in flower at Christmas; Mrs. Thomson, white, flowers slightly incurved; and King of Plumes, a pretty variety with yellow flowers, the petals being much lacinated, give a charming effect of great lightness.

THOMAS SMITH,
Coombe Court Gardens.

SINGLE CHRYSANTHEMUM ROBERT THORPE, A BEAUTIFUL VARIETY WITH WHITE FLOWERS.

Butler's Caprice, an intermediate shade between the last two. White Cap and Yellow Cap are similar except in colour, which the name indicates. Market Red follows with flowers of a velvety red; Thomas Moore, rich wine red; Mrs. W. A. Read, rich bright crimson; Mrs. Rider Bird, a fine shade of fawn; and Freda Bedford, a faultless shade of pure apricot. Foxhunter gives flowers of a rich glowing crimson shade, resembling the well-known Mrs. J. H. Silsbury. Dazzler is a deeper shade of crimson, also having petals of great substance. West Hall Crimson is stiffer, with reddish crimson

of the air is used up in the process of respiration, not only by the roots, but also by the vast population of germs that inhabit the soil, certain waste products of a poisonous nature are produced, and these must be removed or rendered harmless if the soil is to be kept fit and sustained at its highest point of efficiency. Lastly, a fertile soil must be able to take up the sun's heat and retain it. Warmth is of supreme importance, and especially so in spring. If at times the land is too wet, the heat is absorbed by the useless water, and the soil remains cold and unpropitious to early growth.

SCIENCE IN RELATION TO HORTICULTURE.

AUTUMN CULTIVATION OF SOIL.

What is Fertile Soil?—It is generally recognised that autumn cultivation of soils has a beneficial effect upon fertility. Let us consider the subject from the point of view of the requirements of crops. It will make the central facts clearer, perhaps, if we first of all consider the chief properties of a fertile soil. It is required of a good soil that not only will it afford a safe anchorage for the roots of plants, but that it must give, during the growing season, a constant supply of water to the transpiring foliage. Furthermore, it must be able to yield up to the feeding rootlets all those different mineral constituents, such as phosphates and salts of potash, as well as those simple compounds of nitrogen (nitrates or salts of ammonia) that are absolutely required by all garden crops. There is another condition that is sometimes unremembered by cultivators, and that is, the capacity of the soil to hold air, and yet this is one of the most essential aids to fertility. Ventilation is just as important for soils as it is for ordinary dwellings, as in the absence of pure air the active living roots of our ordinary cultivated plants would sicken and perish. Moreover, as the oxygen

The Value of Digging.—Now, how does cultivation affect these conditions of soil fertility? The one great mechanical effect of digging is that it makes the soil finer in grain, and the finer the grain the greater is its fertility. To appreciate fully the importance of this fact, let me refer for a moment to the way the roots of a plant feed. It is well known that all food taken up from the soil must be absorbed in solution in water. No solid particle, however minute, can pass through the membrane that acts as a covering to the young roots and root-hairs. But it is a peculiarity of all tillage plants that their roots are slow to take up what we may term "loose" water, that is, water that is free to drain away from the soil. The water they really take in is the water that clings to the surface of each little damp particle of soil, as such water is more highly charged with food slowly dissolved out of the little solid mass to which both the film of water and root-hair are so closely attached. Ordinary digging tends to break up the soil into a finer mechanical condition, and so tends to increase its water-holding power.

Autumn Cultivation carries the crumbling process much further, especially in the case of heavy or stiff soils. By throwing up the soil in rough ridges, the frosts of winter, by freezing (and therefore expanding) the water within the pores of the soil, causes the coarse lumps of soil to swell, and because of this pushing apart of its particles, cohesion is weakened and their former closeness of texture is destroyed. The ridges quickly dry out in the March winds, and are easily pulverised when spring operations begin in the garden. This expansive force of freezing water is, by far, the most powerful agent at the gardener's disposal for the breaking down of lumpy soil, and so for converting it into a mellow and kindly workable condition, and neglect of this relatively cheap and easy method of increasing fertility is a refusal to take advantage of one of Nature's most generous offers to aid the gardener in his efforts to secure the best services of the soil in the bountiful production of crops.

Cultivation and Fertility.—Having thus briefly referred to the method by which the soil may be reduced to a fine condition, we may now consider a few of the advantages arising from such work. But first it may be well to remark that a gardener should always remember to think in terms of area of soil particles available for exploitation by roots, rather than in terms of superficial area of his garden. A well-tilled plot of a rood area may be quite as productive as a badly-tilled plot of an acre, as it all really depends upon the fineness of the soil. A little hard cube of soil will have six sides or surfaces. If it is broken in two, the six sides become twelve, and if these two are again divided, there will be twenty-four sides, over each

of which a water film can cling, and so the work of dissolving out plant food substances from the soil can be extended over four times a greater area in the last-mentioned case than in the first. In fact, a cubic foot of soil such as is used for potting purposes represents in reality about an acre of absorbing area for roots. As long ago as the year 1733 the father of tillage husbandry, Jethro Tull, when advocating the thorough cultivation of soils, referred to this extension of the absorptive area as the "root-pasturage," and so in sober truth it is. Remembering that all garden soils contain practically an unexhaustible supply of plant food, if only it could be made available, and also that the only natural way

THE NEW DOUBLE-FLOWERED VARIETY OF PRIMULA MALACOIDES.

in which it can be so made ready for the roots is through the dissolving action of tightly-clinging water films, it follows that fining the soil is equal in effect to manuring it. Furthermore, such thorough cultivation, by increasing not only the water-holding power of the soil, but also its air-holding capacity, encourages the growth and general activity of useful bacteria in the soil, and especially such forms as are engaged in the work of nitrification. Closely associated with this method of soil improvement is the important question of liming; but a consideration of this particular aid to fertility must be held over as the subject of the next article.

DAVID HOUSTON.

Royal College of Science, Dublin

NEW AND RARE PLANTS.

AWARDS OF MERIT.

Chrysanthemum Maud Jeffries.—A decorative Japanese variety of the purest white, and one of the most valuable of these for late flowering and conservatory decoration. A large group in small pots was sent by Colonel the Right Hon. Mark Lockwood, C.V.O., M.P., Bishop's Hall, Romford (gardener, Mr. Craddock).

Violet Kaiser Wilhelm.—A large and spreading flower, paler in colour than La France, with sweet perfume. The variety has very long stalks, and is quite distinct. Shown by Mr. T. Johnson, Shaftesbury.

Chrysanthemum Cardinal.

—A single-flowered sort of rich bright crimson colour, with big, conspicuous, golden yellow centre. Not more than 2½ feet high as shown. The rich colouring is brilliantly effective in the fullest light. From Messrs. James Veitch and Sons, Limited, Chelsea.

Begonia Rosalind.—This newest addition to the winter-flowering section is a great gain in colour, which is pure rose, the only one, we believe, of this precise shade. It is possessed of the same dwarf habit and freedom of flowering as Syros and Emta, and will make for these a good companion plant. It was raised from *B. socotrana* and a white-flowered, tuberous-rooted variety. From Messrs. Veitch and Sons, Limited, Chelsea.

Chrysanthemum Commodore.

—A fine crimson-coloured, single-flowered variety of good size and substance, though less brilliant than Cardinal. From Mr. T. Stevenson, gardener to E. Mocatta, Esq., Woburn Place, Adlestone.

Primula malacoides II.-pl.

—Just a semi-double-flowered form of the now well known and deservedly popular Chinese species, varying nothing in colour, habit of growth or freedom of flowering. This and the type make ideal pot plants for the cool greenhouse. From Bees, Limited, Liverpool.

NEW ORCHIDS.

The choicest of novelties was seen in the lovely *Cattleya* named Maggie Raphael The Dell Variety, sent by Baron Schröder. The flowers

were ivory white, save for the lip, which was royal purple, with gold markings in the throat. It was unanimously granted a first-class certificate. Each of the following received an award of merit: *Cattleya* Mrs. Temple variety Dreadnought, from Mr. C. J. Phillips, Sevenoaks; *Cypripediums* Goliath and Strelsa, from Mr. W. R. Lee, Heywood, Lanes; *Laelio-Cattleya* Auto-Dom, from Messrs. J. and A. McBean; *Odontoda* Latona Goodson's Variety, shown by Mr. H. S. Goodson of Putney; and *Odontoglossum* Saturne violaceum, sent by M. Henri Graire, Amiens.

The foregoing novelties were shown before the Royal Horticultural Society at the meeting held on December 2.

GARDENING FOR BEGINNERS.

THE AMATEUR'S GREENHOUSE IN WINTER.

THE furnishing of the greenhouse or conservatory during the winter months is a comparatively easy matter in an establishment where propagating and growing houses are at command to keep up regular supplies of flowering plants. The amateur, as a rule having no such auxiliary houses from which to draw his supplies, must to a great extent rely on plants that can be grown outdoors during the summer months, or possibly on what he can produce with the aid of a few cold frames; nevertheless, even with such limited means, a good variety of plants can be produced for the winter embellishment of the greenhouse. It is a great advantage if a hot-bed of leaves and stable manure can be used for the raising of seedlings and cuttings during early spring. In such a frame, or even in the greenhouse itself, such plants as Cinerarias, Chinese Primulas, *Primula obconica*, *P. malacoides*, Chrysanthemums and Salvias for late autumn and winter flowering can easily be raised.

The Cinerarias and Primulas can be grown in cold frames all the summer and removed indoors in the autumn. Such plants as Chrysanthemums and winter-flowering Salvias, which pass their initial stages in the greenhouse or cold frames, are stood outdoors all the summer; in fact, some of the later-flowering Chrysanthemums may stand out at the bottom of a wall until the beginning of November, especially if a piece of scrim canvas is placed over them at night. Here I would advise amateurs to grow a quantity of Chrysanthemums in 6-inch pots, rooting the cuttings about the middle of March. The Caprice du Printemps type, such as Kathleen Thorpson and White and Yellow Cap, are very suitable for this purpose, as also are many of the single-flowered sorts that are now so popular. Darenth Jewel, Norma, Miss Olive Prater, Robert Thorpe and Mary Richardson are all good sorts.

Cyclamen are very useful for the greenhouse, as they produce their flowers for a period of several months. They are generally sown during August of the previous year; but the amateur would do well to sow earlier, say, about the middle of July. This would give stronger plants for the winter, a great advantage where not much heat is at command. The following spring they can be removed to a cold frame and be grown there all the summer.

Arum Lilies are favourite subjects, and have the advantage of being able to be grown outdoors all the summer and dried off and potted up again at the end of the summer, or they can be planted out and lifted during the autumn. This latter method is a distinct advantage for the amateur, as he thus starts the winter with a good ready-grown plant, which, with liberal feeding, will produce flowers for several months. The accompanying illustration depicts a pretty arrangement of Arum Lilies and the blue winter-flowering

Coleus thyrsoideus, with plants of *Magnolia conspicua* at the back. The *Coleus* can be raised from seed during the spring or from cuttings put in about the beginning of June, and should be grown in a cool greenhouse during the summer. It requires careful attention as regards watering, as it is apt to lose its lower leaves if neglected in this respect.

Bulbs are very useful for winter and early spring flowering. The most popular are Freesias, Narcissi (especially the Paper-White Narcissus, which can be had in flower from November onwards), Roman Hyacinths and the large florist's varieties, and Tulips of various sorts, starting with Van Thol's, other good early sorts being Vermilion Brilliant, Mon Fresco,

to them during the winter. The same applies to the Cape or Scented-leaved section, which are favourites with many amateurs, as also are Cacti or succulent plants, which require very little water in the winter. During that period all watering, as far as possible, should be done in the morning.

Foliage Plants.—Quite a variety of beautiful foliage plants can be grown in the cool greenhouse, and many of them prove useful for the decoration of the dwelling-house. Chief among them are such plants as *Aspidistra*, *Asparagus plumosus*, *A. Sprengeri* (this is good for baskets), *Cyperus alternifolius*, *Cordyline australis* in several varieties, and *C. stricta*. Many cool-house as

ARUM LILIES, COLEUS THYRSOIDEUS AND MAGNOLIA STELLATA GROUPED FOR WINTER EFFECT IN THE GREENHOUSE

Keizerskroon and King of the Yellows. Good early-flowering sorts of Narcissi other than the Paper-White are Henry Irving, Golden Spur, Van Sion, obvallaris, Horsfieldii, Sir Watkin and odorus rugulosus.

Success in flowering bulbs early depends to a great extent on their being well rooted, and that means they must be potted early. Freesias and early Narcissi should be potted from the middle to the end of August, and Tulips from the beginning to the middle of September. They should be stood outdoors and covered with well-weathered ashes, leaf-soil or Cocoanut fibre until they are well rooted, when they should be removed to the cold frame or cool greenhouse.

Chrysan are useful plants, and are quite happy in a cool greenhouse, keeping them on the dry side during the winter. Pelargoniums of the Zonal type should be given the driest and warmest part of the house and not be over watered, for too much moisture at the root proves fatal

well as hardy Ferns prove very useful for the amateur's greenhouse during the winter. Helxine Soherohi is very useful for draping the edge of the stage. Azaleas of the indica type are very useful, especially such as Deutsche Perle, which can easily be had in flower by Christmas. Bouvardias, Acacias and various Heaths are useful for winter flowering, while a few plants of *Boronia megastigma* should be grown for the sake of their fragrant flowers. Such plants can be purchased very cheaply every season, as they are slow and difficult to grow from their initial stages. Speaking generally, the larger flowering shrubs, such as *Magnolias* (shown in the illustration), Prunuses, Rhododendrons and the like, cannot be accommodated in the small greenhouse, at the same time Azalea Deutsche Perle and similar varieties, together with Deutzias, Bouvardias and innumerable Heaths should find a place in the amateur's greenhouse, however small it may be.

J. C.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Pleasure Grounds.

Tree Felling.—Care is necessary in taking down large trees, and it is wise to employ experienced men for such a purpose rather than to risk damaging the surrounding trees which one is endeavouring to maintain in good condition.

Care of Trees.—Old trees should be systematically gone through every two or three years, removing any dead wood that may be in them. This is especially necessary if they are situated where they may be used for sitting under during the summer months. Such trees as Weeping Birch, Beech and Ash must, naturally, be left, so that the trees develop and exhibit their pendulous habit of growth; but other trees that have a good spread of branches may with advantage be trimmed a fair distance up the main stem, thus allowing air to penetrate beneath them. By doing this the grass may be kept in fair condition by mowing; but where the branches are allowed to come too near the ground, the grass will naturally die and thus prove an eyesore.

Plants Under Glass.

Perpetual-Flowering Carnations. These have bloomed well during the autumn, no doubt owing to the mild, open weather. Go over the plants as often as may be necessary, tying in the young growths and disbudding the bloom-buds to one to each shoot. Under certain conditions the surface of the soil is apt to get a little green at this season of the year, but an occasional scratch over with a label or something similar should keep it clean. If allowed to accumulate it robs the roots of much necessary air, and the plants are apt to become sickly.

Primulas.—These are now making a good show—at least the earlier batches—and, to keep them throwing up strongly, an occasional sprinkling of Clay's Fertilizer may be given. This adds colour to both flowers and foliage. Valsol, also, I find a good manure at this season, but it must be used very sparingly.

Begonias Gloire de Lorraine.—These appear to be lacking in colour in many places this autumn, and I cannot help thinking that if they were given a little less heat as the flowers open and a little manure as advised for the Primulas, they would not be so insipid in appearance. Plants that have been in bloom some time should have the stale blooms removed, as these only tend to make the plants look dull and of poor colour.

Bouvardias.—The older plants of Bouvardias in many instances will be going out of flower, and unless there is sufficient young growth coming along that is likely to produce bloom to warrant their remaining in the intermediate house, they should be removed to a cool one. The younger plants are usually more continuous in growth, so they should be kept going to provide material for button-holes or for small vase work, for which purposes they are very useful.

Gardenias.—These are much appreciated during the winter months, and plants that are pushing their flower-buds must be fairly liberally treated, both as regards heat and moisture, to ensure their opening kindly. Too low a temperature at night after the buds reach a certain stage often tends to make them drop. As these plants are very liable to be troubled with insect pests, they must be periodically sprayed with an insecticide to keep them down.

The Vegetable Garden.

I have already advised in these columns the necessity of pushing on with all groundwork while the weather is open, but it must be borne in mind that some soils are very much better left alone if in a very wet condition, this applying generally to very heavy soil, and I find that here in the Thames Valley, where the ground is sometimes apt to be flooded, trenching in the month of February is often more remunerative than autumn trenching. In the event of very severe weather, manure and leaves should be wheeled on to the ground, and even if the ground is hard only for an hour or two in the morning, it is advisable to do this work then rather than when it is soft, and thus avoid cutting

up paths and making a mess generally. Further heaps of hot-bed material also may be prepared, as with the turn of the year it will be necessary to get many of the early vegetables on the move.

Fruits Under Glass.

Peach-Houses.—By this date all the Peach trees should be quite ready for pruning, though I have found the leaves hang much longer this season than ever before. The cleansing of the trees and the houses must be continued as time permits, as even late Peaches are apt to push their buds quite early in the year, and it is advisable to get the work finished before the trees reach this stage.

Vine Borders in newly-planted houses that need extension should be attended to as early as possible. Wherever it is convenient, the soil should be prepared under cover, so that, when it is being put on, it is not in too wet a condition. Soil in a sodden state is apt to go sour, especially if it is trodden in as firmly as is desirable. Frozen soil also should be avoided. Too large a mass of soil added to a border is also undesirable, a foot or 18 inches in width being quite sufficient at a time, as, once the border is completed, the only means of enriching it is by annual top-dressings, and by this means it can quickly become too high for practical purposes.

The Hardy Fruit Garden.

Pruning.—After the shutting and planting are completed, a start should be made with the pruning, preferably with the wall trees, and too great care cannot be exercised in this direction, as in many instances the different varieties of Apples and Pears need a very different system of pruning. It is quite advisable for the head-gardener to superintend this work himself, unless he has a man who is thoroughly well up to the work and understands the requirements of the individual varieties. An effort should always be made to keep the spurs on the wall trees as short as possible, there being nothing gained in allowing these to become long. If a fruit-bud or two can be secured near the base of the spur, the rest may be cut away with advantage; in fact, where the spurs are pretty close together, here and there one may be cut back to a wood-bud each season to keep up the supply of young spurs.

THOMAS STEVENSON.

(Head-gardener to E. Mocatta, Esq.)

Woburn Place Gardens, Adlestone, Surrey.

FOR NORTHERN GARDENS.

The Flower Garden.

Erica carnea.—This precious Heath, flowering from February to May, should be freely planted, not only in the Heath garden, but along the edges of mixed beds and borders of herbaceous flowers. I once saw a bed entirely filled with it in a File-shire garden on a lawn, and although it is over thirty years ago, the impression produced on my mind has never faded from my memory. Unlike Heaths generally, it is not at all particular as to soil; but if a little peat or flaky leaf-mould and sand can be given to it, it will be grateful for the attention. It can be planted now in open weather. The white variety, generally known as *E. herbacea*, is also very attractive.

Propagating-Boxes.—Those situated near centres of population can often get disused dry fish boxes ready to hand very cheaply, or it may be a type of box which can be sawn in two longitudinally, and thus form two useful boxes, with the lid nailed on one-half to form a bottom. Where boxes have to be made, three-quarter-inch planks should be used, and a suitable size for most purposes is 30 inches by 15 inches by 4 inches. Of course, light plants like Lobelias do quite well with a depth of 3 inches, while East Lothian Stocks require about double that depth. Give them ample drainage.

The Rose Garden.

Forming Pergolas.—Climbing Roses, and especially the wickhamianus, can be grown in a variety of forms, and the pergola is one of the most pleasing in every way. Although the hardwoods produce the most natural effects for pergola

construction, yet, with the exception of the Oak, they are not very durable, and if I had a choice I would use Larch or Oak. The paved pathway is perhaps as good as any, laid irregularly. Above all, a sufficient root-run of good, deeply-wrought soil must be provided for the Roses, or good results need not be looked for.

Plants Under Glass.

Chrysanthemums.—All plants as they go out of bloom should be cut over, and the plants placed in as light a position as possible to ensure firm cuttings. These remarks, of course, chiefly refer to the singles and decoratives. Some of the large-flowered Japanese varieties are very shy in producing cuttings, and where sufficient stock has not been received of any of these, the surface soil should be carefully pricked over, and the plants receive a top-dressing of rich soil to encourage the production of cuttings.

Potting Liliun auratum.—After the bulbs come to hand, no time should be lost in potting them up. For single bulbs, pots 7 inches or 8 inches in diameter (according to the size of the bulb) should be used. Drain the pots thoroughly, and use a compost of turfy loam and peat, flaky leaf-mould, dry horse-manure and sharp, clean sand, all in about equal proportions. Use the whole in a rather rough state, pot loosely, and leave ample room for subsequent top-dressing. Give a slight watering and keep rather dry till growth commences. Place in a cool pit or frame.

Forcing Plants.—Batches of these should be introduced to the forcing-house from time to time, placing those newly introduced in the cooler end of the house. Tulips should be shaded from the light till the flower-stems are a good length, otherwise they will be short and dumpy. Do not allow the night temperature to rise much above 60°. Damp the house about midday with a fine spray.

Fruits Under Glass.

Early Strawberries.—Where ripe fruits are wanted by the middle of March, a small batch may now be introduced to the forcing-house. The plants should be taken to the potting-bench and all decayed foliage be removed. The drainage ought then to be seen to, and where the surface soil looks sour the plant should be turned out, the drainage rectified and the plant carefully returned to its pot. The surface soil of the whole batch must then be pricked with a stick, after which the plants ought to receive a surface-dressing with horse-manure, which should be watered in. Place the plants in the forcing-house and maintain a minimum temperature of from 45° to 50°, with a rise of from 5° to 10° during the day.

The Hardy Fruit Garden.

Supporting Bush Fruits.—On heavy, rich soils, and especially in the vicinity of trees, certain varieties of Gooseberries and Currants are apt to lurch over. Any such should have attention as soon as the bushes have been pruned and the weather permits. Prepare a sufficient number of forked branches of moderate thickness; then ease the soil at the neck of the bush with a digging fork, replace the bush in a perpendicular position, and on the side to which the bush is inclined insert the single end of the support in the ground at a slight angle, fit the fork under the most convenient lower branch, and firm up the soil round the neck again.

Pruning and Training Wall Trees.—This work should be pushed through as speedily as possible, as we generally get our severest weather during January and February.

The Vegetable Garden.

Rhubarb and Seakale.—Batches of these should be introduced to heat to be forced from time to time.

Foot-Scrapers.—There should be a plentiful supply of these in the garden. A useful home-made scraper can be produced as follows: Procure two pieces of Redwood 3 inches by 2 inches, point and tar them, drive them fully halfway into the ground at about a foot apart, make an incision about one and a-half inches deep on the top of both simultaneously with a saw, then force a light bar of iron cut to the required length into each incision, and the foot-scraper is finished.

CHARLES COMFORT.

Broomfield Gardens, Davidson's Mans, Midlothian.

GARDENING ACROSTICS.

As announced in our issue for November 22, we are publishing eight gardening acrostics, to be divided into two sets of four each. Each light correctly guessed will count one, and also each "first" and each "last." Thus, supposing the whole is China (firsts), Aster (lasts), the full marks will be seven—one for China, one for Aster, and one for each of the five lights C . . . A, H . . . S, I . . . T, N . . . E and V . . . R. Hence, suppose a competitor got everything right but the light I . . . T, he would count six, and it would not matter if he attempted to solve that particular light or not.

Those entering for the acrostics must observe the rules published on page 607 of last week's issue.

DOUBLE ACROSTIC No. 2.

Firsts—Two fruits are more than brothers, I am the "Esau."

Lasts—A succulent apocarpous fruit—sometimes red and sometimes yellow—e.g., Yellow Antwerp and Red Antwerp.

1. A small genus of aquatic herbaceous plants with yellow flowers, natives of the northern temperate hemisphere.
2. A once-popular genus of hard-wooded South African evergreen shrubs.
3. One of the heaviest, oldest and best flavoured of the white "berries" of show-land.
4. "Avec les curieux elle passe pour l'Impératrice des fleurs et la plus belle production de la Nature."
5. A race who stamped out the Vine, but introduced the Lemon and the Orange.
6. Although I had had millions for generations, I was not a "world product" until after my introduction to the New World.
7. In an epigynous flower, what is the position of the ovary?
8. Pearls in an imperial crown.
9. What is obtained from *Diospyros ebenum*?

Solutions of the above must be sent so as to reach the Editor at 29, Tavistock Street, Covent Garden, London, W.C., not later than the first post on Saturday, December 20. Mark the envelope "Acrostic" in the top left-hand corner.

THE FRUIT GARDEN.

AN IDEAL ORCHARD FOR A SMALL COTTAGE HOLDING.

Manuring the Soil for Young Trees Before Planting.

A word as to the economy or otherwise of this custom. The object the planter should set out before him is the production of that sort of shoot growth on his trees which will secure to him the best and heaviest crops of fruit. The question will naturally be asked, "What sort of growth is this important growth in which we are in quest of?" I answer that it is that growth of moderate strength, neither too strong nor too weak. Such a growth as this is matured and hardened fairly early in the season, affording ample time in late summer and autumn for the plumping up and ripening of fruit-spurs and flower-buds; whereas, if the growth is overstrong, the chances are that in our short summers it will often be found difficult, and sometimes impossible, to properly ripen such wood, with the usual result of barren trees and branch growth stronger than ever, needing recourse in a few years' time to root-pruning before such trees can be brought to a fertile condition. On the other hand, too weak a growth is a loss on all sides, and leads only to failure. Therefore, as I pointed out before, the safe course to follow is to forbear to manure on good, deep loams, and to manure moderately on lighter and poorer land.

Distances Apart at which Trees Should be

Planted.—The trees which pay best to grow (not speaking of bush trees) are Apples and Plums, and the best way to plant these is to put them alternately in the row, for the reason that Apple trees live longer, make larger trees and remain longer in profit than do Plum trees. The Plum trees, when signs of failure or decay set in, can be grubbed up and the extra space given to the Apple trees, of which by then they will have need. I advise that the Apple trees (standards) be planted 20 feet apart in the row; this will take fifty-four trees to the half-acre. Of Plum trees, which should be planted between the Apple trees in the rows, there will also be fifty-four trees, making in all 108 standard trees for the orchard. The distance between the rows of Apple and Plum trees should also be 20 feet. This space for many years over the greater part of the orchard may be profitably planted with bush fruit trees. Of these I will speak later.

Planting the Standard Trees.—The holes or spaces for planting being now ready to receive the trees, let us consider for a moment the points to look for in a healthy, promising young tree. It will be time well spent and space economically used, as unless your trees are of the best at the start, it is hopeless to expect success in after years. In the first place, I would say, purchase your trees of a responsible firm of fruit tree growers with a reputation to maintain. On no account have anything to do with cast-away trees sold at auction sales. Usually they would prove too dear at a gift. Go and select the trees yourself if you can and are competent to choose the best; if you are not, take a friend with you who is. Choose a standard tree with a straight, young stem with a clean, shiny and a healthy-looking bark. A tree with bark which appears dry and cracking in many places, with twists and big knots on its stem, you must fight shy of. Three year old trees from the time of grafting or budding are the best to plant. By then they will have

fair-sized heads already formed, and a foundation laid for a permanent system of branches by those who are skilled in the work.

Planting the Trees.—Let the soil already in the holes be torked over a few inches deep; then prepare a bed to lay the tree in. This is done by torking out a hole in the middle slightly larger than the roots of the tree when slightly shortened will occupy. This should be about ten inches deep and slightly concave in form, the object in view being that the ends of the roots should have a tendency to grow upwards rather than downwards, surface roots being of so much more importance in fruit production than are roots pointing down towards the subsoil. See that the bottom of the hole is firmly trodden down to receive the tree, choosing a dry, fine day for planting. Do not plant in wet weather. The next thing to do is to take the tree in the left hand, and with a sharp knife shorten its roots—the stronger ones, if they are above a foot in length, to shorten to this length, and the smaller and finer roots to have their tip ends only shortened, any broken or damaged roots to be cut back below the damaged parts. There is a right and a wrong way of cutting these roots. The right way is to cut them so that the cut side will face upwards, not downwards. The young roots formed next summer from the cut part facing upwards will have a tendency to grow upwards, and those formed on the part facing downwards would have a tendency to grow downwards, with detrimental results, as pointed out above. Press the tree gently into the centre of the hole, and then carefully cover in the roots with the finest of the soil in the first place, filling all open crevices with the hand. Arrange for the larger and lumpy pieces to be placed round the sides. The new roots made in the spring and summer will soon find them out, and greatly benefit as a result. When the hole is filled, tread the soil firmly down. Its surface should be an inch lower than the level of the surrounding land. Too deep planting must be avoided, and the best way of doing so is to plant the trees the same depth as they were previously planted in the nursery. This is always plainly indicated on the bark of the tree by a dark ring at a point which was previously level with the surface soil; but, as a rule, 10 inches deep is the correct depth to plant.

Mulching the Trees.—A mulch, 3 inches deep, of well-rotted manure should be placed on the surface of the soil round each tree as far as its roots are supposed to extend. The essence of this manure will be washed to the roots by winter rains, enriching the surface soil and encouraging the formation of many indispensable surface roots. This mulch should be slightly added to in April. It will be invaluable in reducing evaporation from the soil, in keeping the soil moist, and in feeding the surface roots during summer.

Staking the Trees.—Strong stakes that will keep the trees well in position, and that will last for at least three or four years, should be used. They should be as long as the stems of the trees and be secured to the trees by three ties, one within 2 feet of the bottom, one in the middle, and one within 3 inches of the top. There is nothing better with which to tie the trees than moderately thin tarred twine. The twine should be first coiled round the stake before it is placed round the stem. This will secure the tie in position, preventing it from slipping either up or down. A thin strip of cloth an inch wide should be coiled round the stem of the tree where the ties are to protect the bark against injury from

THE EDITOR'S TABLE.

Hardy Flowers from South-West Scotland.—Mr. R. Findlay, Logan, Stranraer, sends a box of shrubby Veronicas and a hardy Eupatorium which are now flowering well in many gardens. The flowering spikes, remarkable for their freshness, were sent on November 28 with the following note: "I have the pleasure of sending you by post a few sprays of Veronica and also of Eupatorium wienmannianum. They were all cut from the open garden to-day. The plants of Veronicas are quite a sight at present. Gauntlettii and mel drumensis are the freest to flower here in autumn. I am sorry there is no flower on Veronica macrocarpa, which is one of the very best. These late-flowering shrubs are so useful in this mild district in grey November. Eupatorium wienmannianum has done very well this year."

tying. During the following summer these ties should be examined to see they are not too tight, as the stems of healthy young trees swell rapidly. The foregoing treatment applies to both Apple and Plum trees.

OWEN THOMAS, V.M.H.

(To be continued)

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR of THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

THE GREENHOUSE.

SALVIA NEMOROSA VIRGATA (E. B.) The plant would be quite safe in the herbaceous border, though its greater beauty would, we think, be best revealed by planting it in a group or bed apart.

NAMES OF CHRYSANTHEMUMS (L. J. H.)—We are able to name several of the varieties you have sent us. Those we have not named are much out of character. No. 1, White Quintus; No. 2, Bronze Soleil d'Octobre; Nos. 3 and 6, not known; No. 4, Commandant Blusset; No. 5, O. J. Quintus; No. 7, Sport from La Triomphante; No. 8, La Triomphante; No. 9, Yellow Triomphante (Sport from La Triomphante); No. 10, not known, very poor quality. It is very difficult to name Chrysanthemums unless they have foliage as well as bloom on the spray sent us.

PRIMULA OBCONICA FAILING (Erlon) A difficult question to answer, particularly as you do not mention whether any other plants are associated with the Primulas, and if so, whether they are similarly affected. A temperature of about 60°—that is, if the thermometer goes beyond it at times, seems rather too warm. We should also consider that once a fortnight is quite sufficient to feed the plants. Is there any means of sulphur fumes getting into the structure in which are the plants? We do not think the presence of iron in the soil would affect the flowers of your Primulas, for, as you say, the plants themselves are in good condition.

A SUPPOSED YELLOW CHRYSANTHEMUM SPORT (W. F. H.) We have carefully looked into the colour and character of the flower which you have been good enough to send us. Although you say it is a sport from Miss Maid Jeffries, we are disposed to think it is identical with F. S. Valis respectively in colour, foliage and form, and we would advise you to make a comparison with blooms, etc., of that variety if you grow it. You should give the plants good cultivation next season, and send the resulting blooms to the floral committee of the National Chrysanthemum Society, who will quickly determine its worth and distinctiveness.

FAIRY-RING SPOT ON CARNATIONS (I. C.) This is caused on Carnations by a cold, damp atmosphere, hence the autumn of the year is more favourable to its development, and plants grown in a low situation are more readily affected than those grown in an elevated one. Britanica is, perhaps, more subject to this disease than any other variety, and all varieties such as Lady Alington which have Britannia blood in them have the same fault. Fairy-ring spot cannot flourish in a greenhouse where the atmosphere is dry and buoyant. It is most essential to remove the affected leaves, as the disease spreads so rapidly, but if the plants are dusted with a mixture of half flowers of sulphur and half unslaked lime its development is checked, and under the right atmospheric conditions it will be exterminated. In bright weather the disease can be destroyed by syringing the plants with a mixture of sulphide of potassium and soft soap, but rain-water must be used.

KITCHEN GARDEN.

SPINACH AND SLUGS (M. H.) We suppose there is no doubt your Spinach has been destroyed by slugs, millipedes are often very troublesome with that crop. The lining (using powdered quicklime) will do more than anything else to destroy the slugs, and dusting with lime, or even with ashes, will render the plants obnoxious to them. It would be well to try watering the plants affected (and the soil about them) with permanganate of potash, 1oz. to one gallon of water.

INJURY TO CELERY AND PARSNIPS (Rosbud) Take care that all the Celery and Parsnip setts are burnt, not allowed to remain on the soil. Treat the soil with kailit when digging and bury the top deeply. Plant the Celery on another site as far away from this as possible next year, and make sure the young plants are kept clean by spraying them with paraffin emulsion at intervals during their growth. We do not think there is anything very greatly amiss with the Celerias, and what is wrong is mostly due to slightly unclean surroundings. Avoid draughts and take great care over the watering. Keep a sharp look-out for aphid attack, and fumigate on its first appearance.

SPANISH CARDOON (L. H.) This plant is known under the scientific name of *Cynara Cardunculus*, and is closely allied to the Globe Artichoke. There is no special date by which the plant ought to be ready for use, and it is usual in places where it is grown largely as a vegetable for the crop to be so arranged that the plants will mature at intervals of a few weeks from early October onwards. At the approach of frost, the plants are taken up and stored in a frost-proof shed or cellar. The earliest crop is usually from seed sown indoors in February or March, the plants being placed in the open in May. Later crops may be raised from seed sown out of doors in May. The finishing of the crop may be determined to some extent by the time of earthing up. As a rule, about three weeks are allowed between earthing up and digging. This is considered quite long enough for blanching purposes.

MISCELLANEOUS.

FUNGUS TO NAME (Rockpaddy) The fungus you send is *Oudemansia aurantia* often called *Peziza aurantia*. It is not rare.

INJURY TO AN ANTIRRHINUM (E. B.) The Antirrhinum is apparently attacked by a fungus, but the plants arrived in such a dried-up condition that we could make out nothing satisfactorily. Will you send us a few more packed in a tin box, in order that we may make a careful examination of them? We shall then probably be able to suggest a remedy.

HORSESHOE FERN (Miss J. B. L.) We regret that we are unacquainted with a Fern known as Horseshoe Fern, but if you could send us a leaf we should have great pleasure in identifying it and could then advise you as to the cultural details. In the meantime, as it is a native of New Zealand, there is little doubt but that it will thrive under the conditions you describe as having been found suitable for other Ferns.

MANURE FOR LAWN (L. J.) Your lawns may be given a good dressing of well-decayed horse-mannure with a dressing of basic slag, the latter being used at the rate of 4oz. to the square yard. A further dressing of bone-meal may be given in spring, using it at the rate of 4oz. to the square yard. Lawn sand sown over the grass in spring will probably destroy many of the weeds, but more good will be done by the manure encouraging the grass to outgrow the weeds. Some of the coarser weeds, such as the Plantains, might be uprooted now before the manure is applied.

CELERY INFESTED (J. J.) The old saying that a stitch in time saves nine was never more true than in the case of the maggot of the Celery fly, for it is scarcely possible to get rid of it after it has lodged itself between the two surfaces of the leaf, as it does at this stage. The best way to make the best of a bad job is to clear away all the worst of the outside bottom leaves, afterwards dredge the plants with soot (not in large quantity), and then to earth up. To prevent an attack, dust the plants slightly over every ten days during the whole of the month of June, while the Celery fly is about. This will prevent the fly lodging in the leaves to deposit its eggs, and save your plants from injury later.

VARIOUS QUESTIONS (W. F. H.) We do not recognise the pests to which you refer, but would advise you to remove the plants from the frame and thickly sprinkle the bottom with the unslaked lime. The sides of the frame may be given a coating of whitewash made of unslaked lime, and applied while still hot. This should serve to eradicate the pests. At the same time, an occasional investigation by the light of a lantern when dark may reveal other enemies than those which you have noticed. The Daffodils should certainly be at once taken inside. If the leaves have appeared through 6 inches of soil, they are almost sure to be so weak at the base that some support will be needed.

WEEDS ON LAWN (E. G. P. H.) There is nothing about the specimens of turf sent for examination to account for the grass turning yellow in the way you mention. The weed described as a coarse-looking grass is *Luzula campestris*, a dwarf member of the Rush family, which is common in grassland throughout the United Kingdom. The other weed is a species of *Polygonum*. The latter weed should be pulled up, but little good can be done by pulling up the *Luzula* if it is generally distributed throughout the lawn. Although the soil looks good, the grass evidently requires some extra food material, and you would be well advised to apply bone-meal at the rate of 6wt. to the acre, with a dressing of well-decayed farmyard manure. The manure may be applied now.

NAMES OF PLANTS.—Miss B. Cummings: 1, *Pietra Iberidifolia*; 2, *Dianthus Caryophyllus* (Rush garden seedling); 3, *Campanula portenschlagiana*;—J. R. H.: 1, *Musc. Jules Grolez*; 2, *Souvenir de la Malmaison*.

NAMES OF FRUIT.—W. J.: 1, Lord Sufield; 2, King of the Pippins; 3, Golden Noble; 4, Susan-Joar Pippin;—J. K.: The fruit arrived all in pulp, and impossible to name.

SOCIETIES.

BIRMINGHAM AND MIDLAND DISTRICT GARDENERS' ASSOCIATION. THE EDUCATION OF A GARDENER.

"At times I feel that I am skating on very thin ice," was the introductory remark of Mr. J. Udall, Instructor in Horticulture to the Worcestershire Education Committee, when commencing his lecture to the members of the above society on the 1st inst. "The Gardener: His Education and Training," he said, although by no means a new subject, was, nevertheless, one which required much serious thought. Gardeners as a body did not occupy the status that they should; therefore they were not paid as they should be. In fact, they were liable to be despised, for their momentary positions were not as favourable as those of many other professions. This certainly was due to the prevalence of many types of gardeners, whose limited knowledge so curtailed their work that it forced them to accept situations at 2s. to 2s. 6d. per week. Then, too, the danger of the lady gardener also rendered their position precarious if they did not possess an adequate education; for those competitors of the fairer sex not only receive a good education, but they have a liking for this work, and also possess the charm of stilling the acidity of the mistress with a little sweetness unknown to most gardeners unless they cultivated good appearance and address. As a groundworker the young gardener should acquire good grammar, accurate arithmetic and legible writing, and, if he wished to prove himself efficient in his calling, a knowledge of chemistry, botany, geography, mensuration, drawing, entomology, and even a slight acquaintance with Latin were all necessary. An absolute essential to real success was in personality, in having acute observation, quick to denote colour, form and proportion, an easy adaptability to environments, and an administrative capacity in which loyalty, honesty, faithfulness, earnestness and truthfulness were combined. A suitable age for the young gardener to commence upon his life's work was from fifteen years upwards, and during the next succeeding years he should attain proficiency by careful continuation of his former scholastic studies by taking up advanced classes in all the important subjects which come within his sphere of requisites. He should be prepared to do all grades of work willingly, from weeding to stoking; he should be methodical, observant and clean; he should learn the propagation of plants as well as the growth of flowers; he should also include a good knowledge of landscape gardening work. Above all, he would be well advised to keep a diary of his daily work and observations from the very outset; thus, he would be able in after years to refer back to much useful information gained by his own experience. All this, said the lecturer, meant long hours of close study and hard work; but to the industrious, diligent follower of this advice there was the reward in after years. Loud applause was accorded to Mr. Udall upon his resumption of his chair, and the many remarks, together with a unanimous vote of thanks, gave evidence of the satisfaction of his audience at the lecture.

THE ANGLO-AMERICAN EXPOSITION, 1914.

HORTICULTURE, ARBORICULTURE AND FORESTRY SECTION. The Anglo-American Exposition which will be held at Shepherd's Bush next year has for its object the celebration in a fitting manner of the hundred years of peace and progress between the English-speaking peoples since the Treaty of Ghent in 1814. As becomes an exhibition illustrative in the fullest possible sense of the activities of two great nations famous for the prominent part they have taken in the advancement of the gardening art in its varied aspects, demonstrations of both American and British horticulture are being organised on as comprehensive a scale as possible. This section of the Exposition is being organised by the Committee of Horticulture, Arboriculture and Forestry, which includes among its sixty members the foremost horticulturists, arboriculturists and forestry experts of the present time, who have also had much experience in the organisation of exhibitions of the highest class. The committee has already made considerable progress, and has formulated a scheme which there is good reason for believing will ensure a representation of horticulture, arboriculture and forestry worthy of the two great nations interested. Adequate provisions have been made for the display of rock and water gardening of the most varied character, which has of late years attained to so high a state of development, more especially in this country. A large area on the western side of the grounds will be placed at the disposal of those who are specially interested in this fascinating branch of the gardening art. Hardly herbaceous plants will not be less liberally provided for, as evidenced by the spacious Court of Progress having been allotted to them, to English formal gardens and Rhododendrons, and here the firms who devote special attention to these important classes of plants will show their taste in arrangement and skill in cultivation.

Roses, in view of their importance and popularity, will have much space devoted to them, and under the scheme the Elfin Gardens will be almost wholly occupied by these fragrant, attractive flowers. Ornamental trees and shrubs, which have had so many valuable additions made to them as the result of the explorations in Western China within recent years, should also constitute a great feature of much interest and usefulness. Indeed, arrangements are being made for the representation of many other classes of plants that can be successfully grown in the open during the summer months.

EDITORIAL NOTICES.

Every department of horticulture is represented in **THE GARDEN**, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

*The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in **THE GARDEN** will alone be recognised as acceptance.*

NOTES OF THE WEEK.

Royal Trees at Chatsworth.—The fine collection of trees at Chatsworth had additional interest added to it on Friday of last week, when the King and Queen each planted a Cedar of Lebanon in the pleasure grounds adjacent to Chatsworth House. An illustrated description of the fine gardens there appeared in our issue of the 6th inst.

Protecting Wallflowers.—In cold localities it is no unusual experience to lose the whole stock of Wallflowers during a severe spell of frost unaccompanied by snow. The risk of this will be greatly reduced if twigs of Spruce or Yew are placed among the plants at about two feet apart. This tends to break the current of cold air, which is the chief factor in working havoc among the plants.

Slugs in the Rock Garden.—At this time of the year much damage is done to plants by slugs, and as these pests lie concealed during the day beneath the foliage of some of the denser plants, the soil beneath them should be heavily dressed with dry wood-ashes, mixed with fresh soot. Two or three dressings of this during the winter will generally be sufficient to stop their ravages, and will afford suitable food for the plants.

Clothing Tree Stumps.—Where for any reason a tree has to be cut out, it can still be made an object of beauty if it is cut several feet above the ground and then covered by some suitable plant. Clematises are suitable for this work, especially *C. montana* and *C. vitalba* (Traveller's Joy). Other plants suitable for this purpose are *Polygonum baldschuanicum*, the common Dog Rose, *Forsythia suspensa* and the common Ivy. It will, of course, be necessary to dig a good pit and fill it with rich soil in order to give the plant a fair start.

Forcing Rhubarb.—Many are under the impression that to get Rhubarb early it is essential to have a high temperature. This is quite a wrong idea, for anyone who has a cellar or similar place, where the temperature is from 55° to 60°, can grow this welcome subject successfully. If the roots are placed close together, soil worked between them and an occasional watering given, they will do well. It is desirable to dig up the roots some time before they are required for forcing, and leave them exposed to the frost. When quicker in this way they will break into growth quicker and give better results than if forced as soon as dug up.

A Giant Dahlia.—When *Dahlia imperialis* was first introduced from Mexico in 1863, much interest was centred around it, owing to its lofty stature. It proved, however, to flower at such a late period of the year that it was useless out of doors, and a very large structure was needed for its accommodation. Such being the case, in time it almost went out of cultivation. Still, given a house sufficiently lofty, it forms a striking

and uncommon feature. It reaches a height of fully a dozen feet, the lower part of the stem being clothed with huge compound leaves, the upper portion consisting of a large branching panicle of blossoms. The individual flowers are bell-shaped and somewhat drooping, while the colour is whitish, marked slightly with red at the base.

Fruit Failing to Set.—The Board of Agriculture and Fisheries are engaged in an enquiry, through their Horticulture Branch, into the failure of fruit trees to set properly through insufficient pollination, and they would be glad to be put in communication with the occupier of any orchard of five acres and upward who has reason to believe that his trees are bearing less than the normal crop over a series of years. Fruit-growers who are planting new orchards are also invited to communicate with the Board at 4, Whitehall Place, London, S.W.

Ornamental Fruiting Plants.—Now that the flowering season is practically over outside, those plants that are grown for their ornamental fruit are appreciated, and help to brighten the garden at what would be otherwise a dreary time. There are quite a number to select from, so that it is an easy matter to get variety for large or small gardens. Aucubas, several Berberises, a number of Cotoneasters and *Cratægus*, *Gaultherias*, *Sea Buckthorn*, *Leycesteria formosa*, *Pernettya mucronata*, *Rosa rugosa* and *Skimmias* are a few of the best.

The Popularity of the Rose.—The report and financial statement of the National Rose Society, presented to the members at the annual meeting in London last week, and a report of which appears on another page, is an eloquent testimony to the ever-increasing popularity of the Rose. In 1908 the membership of the society stood at what was then regarded as the high figure of 3,150, but now it is nearly double that number. Notwithstanding the fact that the Council have expended large sums on literature, prizes and other features, the financial statement is particularly good, and we congratulate the Council on the excellent work they have done and are still doing.

Blue-Flowering Plants in the Warm Greenhouse.—Flowers of a blue tint are always admired, and of those now in bloom *Barleria cærulea* is very pleasing, while a few of the earliest metallic blue flowers of *Eranthemum pulchellum* are also expanded. These will shortly be followed by the rich cobalt blue blossoms of *Coleus thyrsoideus*, which, of comparatively recent introduction, quickly became a universal favourite. The most uncommon of the three plants above mentioned is the *Barleria*, which, as with many other Acanthads, forms a rather erect-growing plant, with the principal shoots terminated by a cone-like head of bracts, whence the flowers protrude. They are of a beautiful sky blue colour, and though the individual flowers do not last long, a succession is kept up for some time from one head. It is a native of India, and is also known as *B. strigosa*.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Rose Mrs. Cornwallis-West.—In my notes to you on this exhibition Hybrid Tea I wound up by asking the question, "Should not this Rose be renamed Lady Randolph Churchill?" I am informed that in making this suggestion I was wrong, and that the Rose in question was named, not after the lady now known as Lady Randolph Churchill, but after Mrs. Cornwallis-West of Newlands Manor, Lymington, Hants, and Ruthin Castle, North Wales, at both of which places it does extremely well. I shall be glad if you will kindly find room for this withdrawal of my remark.—H. E. MOLYNEUX.

Primula obconica Growing Outdoors.—I enclose you a photograph of some *Primula obconica*s growing out of doors, which may interest you. The photograph was taken last week, and shows plants

PRIMULA OBCONICA GROWING AND FLOWERING IN THE OPEN AT HASLEMERE, SURREY.

which stood last winter without protection. They were raised from seed in the spring of 1911 and flowered that winter under glass. In May I planted them out. They bloomed all through the summer of 1912, and through the winter as well, and have flowered constantly up to date. Our elevation is 720 feet above sea-level; the soil is sandy and light. They suffered rather in the dry spell we had in the summer, but did not seem to mind the cold. They are sheltered from north winds by the shrubs behind them.—C. WRAY, *Hill View, Grayshott, near Haslemere.*

Silver-Leaf Disease of Fruit Trees.—I have carefully read the remarks in two copies of THE GARDEN by Mr. Irwin Lynch, and have come to the conclusion that it is a very good scientific exposition of the theory of cause, progress, warning and conclusion; but as for a cure, I fear we must look further afield. None of the many quotations made by Mr. Lynch gives us any clue as to the remedy to be applied for efficacy. As fruit-

growers we are all anxious to know how to get rid of a troublesome pest, and any practical information would be welcomed by a large body of cultivators.—ENQUIRER.

Early Peas in Pots and Boxes.—The note on early Peas, on page 607, issue December 6, is very interesting and instructive. "T. G. J." does well to recommend boxes as well as pots for the purpose, as the plants will do just as well in the former as in the latter. They are not as expensive as pots, in the first instance, but, of course, do not last as long. Good turves are cheaper still, and I have been very successful in growing Peas in them. Flat turves, 2½ inches deep, are large enough in which to raise the Peas that are to be planted out in the open border in due course; but turves 1 foot wide, the same in length, or at most 15 inches, and 7 inches deep, are the kind to use for Peas that are to be retained under glass. A shallow drill is scooped out, the Peas sown and covered with good compost.—SHAMROCK.

The Midland Daffodil Society.—It will be good news to all who are interested in Daffodils, and in

meeting which I think is to be called for 8 on the evening of the first day's show in 1914—JOSEPH JACOB.

Plants Flowering Out of Doors at Goodwood.—As an indication of the mild weather experienced in various parts of the country, many correspondents have sent us lists of plants flowering outdoors in December. The following, sent by Mr. F. Brock, gardener at Goodwood, Chichester, is one of the most interesting: *Abutilon vexillarium*, *Abelia rupestris*, *Achillea alpina*, *A. argentea*, *A. millefolium* *Cerise Queen*, *A. tomentosa*, *Ajuga reptans atropurpurea*, *Alchemilla alpina*, *Alonsoas*, *Alyssum minima*, *A. saxatilis*, *Aloysia citriodora* (*Lemon-scented Verbena*), *Anehusa italica*, *Androsace carnea*, *Anthemis tinctoria*, *Antirrhinum*s (*Snapdragons*), nine florists' varieties; *Arabis albida*, *A. a. flore pleno*, *Arbutus Unedo* (carrying ripe fruits, green fruits and flowers), *Armeria maritima rosea*, *Asperula suberosa*, *Aster Thompsonii*, *Aubrietia Dr. Mules*, *A. græca*, *A. Mrs. Lloyd Edwards*, *A. Hendersonii*, *A. Wallacei*, *Berberis Darwinii*, *Cassia corymbosa*, *Caltha palustris*, *Campanula muralis*, *C. spicata*, *C. Van Houttei*, *Ceanothus azureus*, *C. Ceres*, *C. Gloire de Plantières*, *C. Gloire de Versailles*, *C. Marie Simon*, *Clerodendron Bungei*, *Cheiranthus Cheiri*, *Japanese Chrysanthemums*, three varieties; *Chrysanthemum maximum*, *Chrysogonum virginianum*, *Chimonanthus fragrans*, *Choisya ternata*, *Collomia*, *Coronilla Emerus*, *Cosmea Sutton's Dwarf Miniature*, *Cytisus canadensis*, *Dianthus deltoides*, *D. fragrans*, *Doronicum austriacum*, *Erigeron Asa Gray*, *E. mucronatus*, *E. philadelphicus*, *E. speciosus grandiflorus*, *Fuchsia gracilis*, *F. Riccartonii*, *Gaillardia grandiflora*, *Geranium Endressii*, *Geum Heldreichii*, *G. rivale*, *Gypsophila repens rosea*, *Hamamelis virginica* (*Witch Hazel*), *Helianthemum*s (*Sun Roses*), four varieties; *Heuchera sanguinea*, four varieties; *Hutchinsia alpina*, *Hydrangea hortensis*, *Hypericum ægypticum*, *H. olympicum*, *H. patulum*, *H. reptans*, *Iberis correatifolia*, *I. Pruitii*, *I. saxatilis*, *Jasminum nudiflorum*, *Lavandula spica* (*Lavender*), *Laurus-tinus*, *Lobelia speciosa*, *Lonicera fragrantissima*, *L. brachypoda*, *Linaria alpina*, *L. maroccana*, *Lithospermum prostratum*, *Magnolia grandiflora*, *Mignonette*, *Nepeta Mussini* (*Catmint*), *N. M. superba*, *Nicotiana affinis* (*Sweet-scented Tobacco*), *Nycteria selaginoides*, *Ænothera macrocarpa* (*Evening Primrose*), *Æ. taraxacifolia*, *Odontospermum maritimum*, *Othonnopsis cheirifolia*, *Oxalis rosea*, *Passiflora cærulea* (*Passion Flower*), *Pentstemon Newbury Gem*, *P. White Newbury Gem*, *P. Myddelton Gem*, *Phlox setacea*, *P. procumbens*, *Potentilla nepalensis* *Miss Willmott*, *P. Tonguei*, *Rosmarinus officinalis* (*Rosemary*), *R. prostrata*, *Rhododendron Grand Arab*; *Roses*—*Orleans*, *Jessie*, *Mrs. Cutbush*, *Marquis of Salisbury*, *Grüss an Teplitz*, *Hiawatha*, *Crimson China*, *Pink China*, *Irish Elegance*, *Hermosa*, *Frau Karl Druschki*, *Souvenir de la Malmaison*, *Dorothy Perkins* and *wichuraiana alba*; *Rudbeckia Newmanii*, *Salvia Pitcheri*, *S. Star of Zurich*, *Sedum stoloniferum*, tall German Scabious, *Senecio pulcher*, *Sisyrinchium grandiflora*, *Solanum jasminoides*, *Spiræa Anthony Waterer*, *S. confusa*, *S. Thunbergii*, *Stock Crimson Beauty of Nice*, *Tiarella cordifolia* (*Foam Flower*), *Tritoma Uvaria* (*Red-hot Poker*), *Tropeolum canariense* (*Canary Creeper*), *Verbena venosa*, *V. tenera moorenetta*, *Veronica Autumn Glory*, *V. Andersonii*, *V. A. variegata*, *V. decussata*, *V. Diamant*, *V. salicifolia*, *V. Simon Delaux*, *V. La Favourite*, *V. Bidwillii*, *V. rupestris*, *Vinca major* (*Periwinkle*) and *V. minor*.

the Midland Society in particular, to know that at a special general meeting held at Birmingham on December 10, the president, Mr. P. D. Williams, in the chair, it was decided that the society should go on as nearly as possible as it was in the days of the late Mr. Robert Sydenham, but that there should be no public dinner in 1914. Mr. Herbert Smith, who is now the managing director of Robert Sydenham, Limited, promised that the society should have the same help from his firm in the future as in the past. Mr. C. L. Adams was unanimously elected treasurer and Mr. Watts a member of the floral committee. The new rules of the Royal Horticultural Society relative to awards were adopted, and will be in force at the next show on April 23 and 24. It was decided to perpetuate the memory of the late Robert Sydenham, the founder, by having the words "Robert Sydenham, Founder," engraved on all the medals and newspaper. It is hoped that an annual dinner, to commence in 1915, will be decided upon at the

PRUNING-KNIFE ? SECA-TEURS.

FOR a long time after I took an interest in pruning I had a great dislike to secateurs, looking upon them as a clumsy substitute for a good knife, and suitable only to those very amateurish performers who were unable to make proper use of a pruning-knife; but after a time my opinions became modified, partly through seeing how much secateurs were coming into general use, more especially among the workmen in our own nurseries. Experiment showed that they had advantages in certain cases, and extended use made me quite fond of them, and now I would like to record for the sake of the inexperienced the particular advantages of the two rival tools. There can be no question that to the person who has mastered the A B C of the use of the knife, the pleasure of a good clean cut is greater than the sensation of squeezing through a branch with a pair of specially-made scissors; also the cut is bound to be a cleaner one. Again, one can cut through a much thicker growth with a knife than can be done with secateurs, and leave a clean wound behind which will soon heal over.

Now for the other side. Pruning Roses and Gooseberries with a knife cannot be called a joy; there must always be a drawing of the knife across a branch to effect a clean cut, and it (as will sometimes happen) there should be a slip, the hand of the operator comes sharply away and is sure to be caught by the prickles of the Rose or spines of the Gooseberry; thick gloves may save one, and they may not. With a pair of secateurs there is no drawing action; the blades encircle the branch, and a steady press makes the cut. Here, then, is a case where the scissors easily beat the knife. Again, tancy yourself on the top of a ladder or high set of steps. You require both hands, as a rule, to make a cut with a knife, and it is not everyone who feels comfortable in such a position with nothing to hold on to but the thin twig they are cutting. Now, with secateurs one can take a firm hold with one hand of the ladder or a stout branch while cutting away freely with the other hand; moreover, it one be at all ambidextrous, one is able to prune all within reach of either hand, thus saving time in going up or down and moving the ladder or steps.

I would say, then, to the amateur, "By all means have both a good knife and a good pair of secateurs," for both are useful and add to one's pleasure in doing the work. It seems a great pity that our English manufacturers do not give us a good pair of secateurs at a reasonable price. I think I may safely say that all such tools come from either France or Germany. That good home-made secateurs are made I do not deny, but they are generally sold retail at about 5s. to 7s. 6d. a pair, while very good French or German made ones are retailed at 2s. 9d. to 3s. 6d. If our own makers cannot compete with these lower-priced implements, well, I suppose there is no help for it, and we must go on as we are; but it seems a great pity that some effort is not made to retain what must amount to a very large slice of trade now going abroad.

J. DUNCAN PEARSON

The Nurseries, Lowdham, Notts.

FORTHCOMING EVENT.

January 13, 1914.—Royal Horticultural Society's Exhibition and Meeting at Vincent Square, Westminster.

"THE GARDEN" IN 1914.

AS briefly indicated in our last issue, with a view to still further enhancing the value of THE GARDEN, we are now in a position to state that we have secured for the coming year the services of many of the leading authorities on gardening, who have promised to contribute articles on subjects of which they have made a life-long study. Those of our readers who remember Sir Herbert Maxwell's articles, which appeared some years ago, will, we feel sure, be glad to learn that he has once more promised to contribute an invaluable series of articles to our columns. Miss Jekyll, whose reputation as a deviser of colour-schemes in the flower garden is world-wide, has also kindly promised to write on the subjects for which she is so deservedly famous. It would, indeed, occupy far too much space to state in detail the many articles to be contributed by new and well-known writers; but the following brief summary will serve to indicate their authoritative and comprehensive character. We summarise them tersely as under:

Trees and Shrubs will be fully dealt with by Mr. W. J. Bean, Mr. Dalhmore and others.

Hardy Flowers and Carnations by Mr. R. P. Brotherston, Mr. E. H. Jenkins and Mr. S. Arnott.

Water-side Gardening by Mr. James Hudson.

The Rock Garden by Mr. Jenkins, Mr. Dillistone and Mr. Arnott.

The Heath Garden by Mr. T. Wilson, head-gardener to the Earl of Strathmore.

Hardy Primulas by Dr. J. McWatt

Daffodils and Tulips by the Rev. J. Jacob.

Roses by Mr. H. E. Molyneux, Mr. W. Easlea and Mr. P. L. Goddard. The latter writes specially on "Roses for Town Gardens."

Sweet Peas by Mr. T. Stevenson, Mr. S. M. Crow and others.

The Vegetable Garden will be in the hands of Mr. E. Beckett, V.M.H., and Mr. E. Molyneux.

The Fruit Garden.—Articles in this important section will be contributed by Mr. Owen Thomas, V.M.H., Mr. E. A. Bunyard and others.

Plant Diseases and Treatment of the Soil.—Under the heading of "Science in Relation to Horticulture," Professor Houston, F.L.S., will deal exhaustively with the Treatment of the Soil and Plant Diseases.

Diseases of Bulbs.—Mr. George Masee, F.L.S., whose article on a disease of Narcissus bulbs we reprinted from the *New Bulletin* in our issue for December 6, has promised to contribute an illustrated series on diseases of bulbs.

Lawns.—Mr. Peter Lees, the well-known green-keeper at the Mid-Surrey Golf Club, will contribute articles on the treatment of lawns.

Auriculas, Chrysanthemums, Greenhouse and Other Plants will also be fully dealt with by acknowledged experts.

These are but a few of the special writers who are contributing to THE GARDEN during the coming year. Most of these articles will be accompanied by practical and artistic illustrations. With such a list of important contributors we look forward with every confidence to the New Year. It has always been the aim of THE GARDEN to place before its ever-increasing circle of readers authoritative articles by recognised experts, and we feel, from letters we daily receive from correspondents all over the world, that the success we have achieved is most cordially appreciated.

THE ROSE GARDEN.

ROSE NOTES FROM THE RIVIERA.

THE BEST STOCKS FOR WARM COUNTRIES.

HAVING much enjoyed Mr. Molyneux's Rose notes, which I see have been also read by garden enthusiasts in many countries, I wonder if he can, out of his stores of knowledge, give us some information on the important point of Rose stocks. In England the Briar stock is so generally used, and has, moreover, proved itself so much the most satisfactory medium for the propagation of Roses, that there is little more to be said on that subject. This, however, is not the case all over the world, and contributions on this point will, I think, be welcomed with much interest by those who garden in the Colonies, or even on the Riviera, where now so many good gardens are to be found. Gardening as I do on this last and well-known coast, I have found, to my regret, that the Briar stock is unsuitable to the climate and conditions generally. It suffers severely from the summer heat and drought—so much so that after the first beautiful and brief flowering in spring is passed, the Rose on that stock never does any more good, and generally dies out by the third year. The stock employed by gardeners and nurserymen here is that called "indica major," a strong-growing Rose that withstands the summer drought without suffering, and after the autumn rains starts into vigorous growth at once; hence its value, because it produces the greatly-valued November and December Roses that are the glory of this coast. I have never ascertained its origin with certainty. If *Rosa indica* was one parent, what was the other? This is the Rose used all along the coast as a hedge Rose, and seems ubiquitous in cultivated land. Its wreaths of pale pink, double flowers of many shades of colouring contrast charmingly with the crimson indicas, which are also used for hedges.

The *R. multiflora* hybrid *De la Grifferaie* was much used at one time, but has proved uncertain as a host, for only the strongest-growing climbers live more than a year or two when grafted on it. The native *R. sempervirens* has always seemed worthy of trial on dry and poor soils where it thrives; but it is not sufficiently vigorous, I am told, and cannot compete with *R. indica* major. There is one Rose, however, I should like to recommend for dry and warm climates, and that is *R. bracteata*, the Macartney Rose. Is it used, I wonder, in China, or the Cape, or the Antipodes? It has a more marked influence on the Rose budded or grafted on it than any other stock I am acquainted with, but it suckers badly and has such hooked and piercing thorns that it is called by gardeners "La Rose Cruelle"! It is extremely vigorous and, of course, evergreen in this climate, and has the valuable quality of growing continuously all through the winter, so that Roses on this stock are more continuous also in growth and flower. The curious property it possesses of adding to the depth of colour of any Rose budded on it is shown to a very marked degree in that beautiful but uncertain Rose Georges Schwartz, which attains a richness of tone that is quite unequalled. That curious but picturesque Rose General Gallien assumes a brilliancy and beauty of colour that it never attains on its own roots or on *R. indica* major, but I should call it essentially the amateur's stock as *R. bracteata* takes a year to establish

itself and does not transplant very readily. To those, however—and they must be many—who possess rampant bushes of this Rose, which is so beautiful in itself, I would say: "Bud freely on each strong, succulent growth, and enjoy the result."

Can anyone say why its close relative, *R. sinica*, is quite useless as a stock? Or can anyone say they find it reliable for that purpose? The new Rose, *R. lucens*, of modern introduction, seems a very promising plant in every way, and those who are happy to possess it will, I hope, tell of their experience.

A large number of Roses from the seeds Mr Wilson collected in China are worthy of trial, but not, I imagine, for those who desire winter Roses. They seem to have a very definite resting period in winter, and their bark does not rise kindly when buds are waiting for a stock. The Banksian Rose is well known as a stock for *Maréchal Niel*, and the blooms at first are particularly rich

IN A HAMPSHIRE GARDEN.

SOME OF THE NEWER DECORATIVE ROSES

(Continued from page 620.)

Miss Cynthia Forde (Hugh Dickson, 1909).—In its particular shade of pink, which is generally termed "rose," and covers, I suppose, as many roses as, if not more than, any other shade of colour that one could name, I am inclined to place *Miss Cynthia Forde* at the head of them all as the best bedding Rose of this colour, even in front of that fine old variety *Caroline Testout*, for so long the most popular garden Rose. It is, I think, a more beautiful Rose, of a more pleasing shade, not perhaps a better grower, but certainly more sweetly scented. I do not know its parentage, but it is nearly ten years ago since I first made its acquaintance at Belmont, and it then struck me as having a good deal of *Antoine Kivoire* blood in its veins. Be that as it may, it is

Viscountess Folkestone, and I am inclined to think it is a better Rose than any one of them. A fine grower, not unduly subject to mildew, and a very free-flowerer, it is destined to become very popular when better known. Named after the wife of a very enthusiastic Rose amateur and exhibitor (and one of the vice-presidents of the National Rose Society), and who herself has won many prizes for table decoration and in the other decorative classes at the National Rose Society's shows.

Mrs. Arthur Munt (Alex. Dickson and Sons, 1909).—A good creamy white garden Rose, strongly Tea-scented, that somehow is not so much grown nor so well known as its merits deserve. A compact, but not a vigorous grower, not subject to mildew; it makes a fine bed, especially in the autumn, when the flowers come as good as in June.

Mrs. Charles E. Allen (Hugh Dickson, 1911).—A charming decorative Rose, pale yellow ochre to buff, very free-flowering, a good grower, not particularly subject to mildew.

Mrs. Charles E. Pearson (S. McGredy and Son, 1913).—It may be considered early to speak or write definitely about this Rose, but I have grown it all this last season, and there is very little fault to find with it. As a pure bedding Rose of its shade of colour it is far ahead of anything else at present on the market. It is a very much improved *Lyon* at its best, the flowers perhaps a trifle smaller and the whole habit of the plant smaller, too. It makes a particularly neat-looking plant, each flower seeming to be produced at the same height from the ground. It is sweetly scented, and has a much better constitution than *Lyon* or the *pernetiana* Roses generally. The colour is a good orange apricot that holds well, flushed on the outside of the petals with red-yellow. If a plant could be taken up and transplanted straight to the centre-piece of a table decoration, it would want no arranging, no stems shortening, the whole being compact and complete.

Mrs. E. Powell (Bernaix, 1911).—This is a very good bedding crimson, of fair shape and size, free-flowering, that is well worth trying; but it is by no means the ideal crimson bedder we are looking for. The blue is too conspicuous in the older flowers.

Mrs. Frank Bray (Alex. Dickson and Sons, 1912).—This is a considerably better grower than *Mme. Ravary*, to which it otherwise has some resemblance, both in the colour of its flowers and foliage; but the former are more freely produced, with a good deal of pink mixed with the orange that enables the flowers to retain their colour better, especially in the autumn, when *Mme. Ravary* is often but a ghost of her real self. I do not think it is at all a case of the one replacing the other; they are sufficiently distinct for there to be plenty of room for both. Delightfully fragrant, and in flower as I write.

Mrs. Frank Workman (Hugh Dickson, 1911).—This is, I think, going to prove a good garden Rose, but it is in a very strong class. There are many good rose pinks. It is free-flowering, carries its blooms well and erect on good, long shoots. Is not predisposed to mildew, and is a good, vigorous grower.

Southampton HERBERT E. MOLYNEUX.
(To be continued.)

(1) HORSE CHESTNUT AND (2) SWEET CHESTNUT TWISTED IN REVERSE DIRECTIONS.

in colour; but I have not heard of Roses generally doing well upon it for any length of time.

It is disappointing to find that, though Roses root so readily from cuttings when put in in August in this climate, there are not many varieties that in the end make strong plants on their own roots—probably because they do not produce enough roots to stand the summer drought and heat. To water heavily during the summer is, curiously enough, the way to kill rather than cure a Rose that is weakly; mulching the roots deeply is by far the better plan. As the natives say, they die of a *coup de soleil* if they are watered when the sun and the ground are so hot. There are difficulties of one sort or another to contend against, wherever your lot may be cast!

La Selva, Brancolor, Nice. E. H. WOODALL.

[We shall be pleased to hear from correspondents who have had experience of the difficulties mentioned by our correspondent. The subject is one of considerable importance to both amateurs and nurserymen.—ED.]

a very excellent Rose, and should be in every garden.

Mrs. Alfred Tate (S. McGredy and Son, 1909).—Another Rose that saw the light of commerce the same year as the last named. Not quite such a good all-round Rose, perhaps, but for some purposes, such as table decoration or a button-hole, even more useful. It has few petals, but its charm lies in its fine colour and beautiful long buds, coppery pink, with a fawn tinge, a good grower, flowers held erect on good, long stems, not subject to mildew, sweetly scented and very free-flowering.

Mrs. Amy Hammond (S. McGredy and Son, 1911).—This is undoubtedly one of the best Roses these raisers have given us. I have grown it now for three years, and each year it has improved. This year it has given me some of the best flowers I have grown, and its autumn blooms were as good as the June flowers. It belongs to the flesh-coloured Roses, and is therefore "up against" *Pharisæer*, *Grace Molyneux*, *La Tosca* and

NEW ROSE Mme. EDOUARD HERRIOT.

TREES AND SHRUBS.

TWISTED TREES.

It sometimes happens with certain trees that the trunks show a marked tendency to twist in a spiral manner. Everyone who is at all familiar with our British trees has probably observed this tendency in the common Hawthorn, a tree often met with in bleak and wind-swept positions, when both trunk and branches bend over with the direction

3.—A TWISTED OAK TREE.

of the prevailing wind. Such trees, if of any age, invariably have rough and gnarled bark, sometimes twisted, as in the case of the Hawthorn depicted in the last of the series of illustrations. The advantage of such a twist is obvious, for just as a rope is strengthened by twisting, so is the tree better adapted for withstanding the strain placed upon it in a wind-swept position.

In the case of the Horse Chestnut (Fig. 1), the twisting is not at all common, and it is really difficult to understand why certain trees possess this peculiarity while others growing under precisely similar conditions are normal. Another point of more than passing interest is the direction of the spiral. In all of the cases illustrated the spiral is from left to right, except in the case of the Sweet Chestnut (Fig. 2), in which the reverse spiral, *i.e.*, right to left, is well defined. This remarkable tree stands in the Arboretum at Kew. The Sweet Chestnut is rather addicted to the production of spirals, which may be in either direction. In the case of the Oak, however, the tendency is by no means common. Fig. 3 represents a derelict Oak in Windsor Forest which has been killed by lightning. Here the twist is observed not only in the main stem, but also running through the branches. In very hollow trees, open on one side, spiral growth is sometimes seen, owing to new wood continually being deposited on its own inner surface. A remarkable example of this curious growth is exhibited in No. 4 Museum at Kew. It is a section of Elm trunk, so hollow as to be merely a shell

a few inches thick. The tree, eventually formed, by its continual growth on the inner side, two remarkable spirals suggesting a pair of scrolls. The Judas Tree (*Cercis Siliquastrum*) is often twisted. An old tree in the Botanic Garden at Cambridge is reputed to be very slowly revolving, so that the branches now leaning to the west were many years ago said to be facing north.

The cause of trees growing in spirals does not appear to be well understood, but one factor which may throw light upon the question is the formation of new cells from the cambium. These cells slide either to the right or to the left as the growth of the tree proceeds. The cells, which are elongated when seen in tangential section, are known as sliding cells, and should they slide equally in both directions, no twisting of the trunk would result. This twisting is worthy of attention at this season, when deciduous trees are in their winter's sleep. C. Q.

COLOURED PLATE.

PLATE 1483.

ROSE MME. EDOUARD HERRIOT.

I SHALL never forget the glorious display of this fine novelty that I was privileged to see

4.—SPIRALS ON BEECH TREE.

at the end of last May when visiting my friend M. Pernet-Ducher at his home, Venissieux, near Lyons. It was a beautiful sunny morning when I was conducted to that part of the famous Rose gardens where Mme. Edouard Herriot was growing, and here row upon row of the healthy-looking plants were in full bloom at this early time of the year. These particular plants were cut-backs, for the thousands of maiden plants in another part were only just showing bud. No one who could have seen the Rose here in its home could have any doubt as to its ultimate success. What a colour! And who can describe it? I guess it will need an artist to correctly name its various tints, but the coloured plate will give some idea of its beauty. As a Rose for bedding and massing, Mme. Edouard

Herriot will be grown by the million in the near future. I was not surprised to learn that M. Pernet-Ducher was obliged to decline many large orders, and, indeed, most of the demands had to be considerably curtailed, for this noted raiser caters for the whole world. The pernetiana Roses have most assuredly come to stay. There are some rosarians who fear that the tribe lacks constitution. I grant that Rayon d'Or and Lyon have a very bad tendency to die back, but this tendency will be gradually eliminated. Certainly with Mme. Edouard Herriot there is no such tendency as far as I have seen, the plants in my possession looking the picture of healthy vigour. We all know how splendidly this Rose was exhibited last year at Vincent Square and Chelsea by that prince of growers, Mr. George Beckwith, and it must prove to be one of the greatest novelties yet raised from a colour point of view. Like most popular novelties, I expect it will be over-propagated, as was the case with Lyon Rose and Rayon d'Or; but no doubt many rosarians have seen, as I have, these two superb Roses sending up wood that could almost be described as timber after they had recovered from this over-propagation.

I have blooming now (December 6) a most charming variety of the group named Mme. Kuan. There is a resemblance to Viscountess Folkestone, and yet sufficient of the Briar suffusion to stamp it as one of the distinctive pernetianas. The flower has a warm apricot hue pervading the pink, altogether a delightful blending.

I saw at M. Pernet-Ducher's quite a number of seedlings of Mme. Edouard Herriot, of which we shall doubtless hear more very soon. There seems to be no end to the variations possible in the cross-fertilisation of the Rose, and no sooner do we have some startling novelty introduced than there are others to eclipse it. In my rambles through the seedling quarters of the three great Irish raisers last July, I noticed quite a number bearing undoubted relationship to the pernetiana group, so that this tribe will soon become one of the most important, perhaps even eclipsing the Hybrid Teas. All readers who wish to add

5.—A WEATHER-BEATEN HAWTHORN.

distinctive novelties to their collections must certainly have Mme. Edouard Herriot, and if they do not yet possess Arthur R. Goodwin, Louise Catherine Breslau, Jessie Easlea and Willomere, I would advise them to get them during the present planting season. DANECROLL.

ROCK & WATER GARDENS.

THE DESIGNING OF ROCK GARDENS.

(Continued from page 621.)

Arrangement of Stone.—

This depends to such a great extent upon the nature of the stone used and the purpose for which the work is being carried out that it is only possible to give a few general instructions. The most important point to remember is that every piece of stone should be placed with due regard to its relation with every other piece in every other respect, competent gardeners, construction of the rock garden. They should be so used. There must be a sense of connection splendid cultivators, and some even with more arranged that they give the impression of being a continuation of the stratification of the adjoining stone. This is really important, many an otherwise good arrangement being spoiled by the introduction of paths formed of another stone altogether, and used in such a way that while they would make excellent paths through other portions of the garden, they are too obviously artificial for the rock garden. With regard to stepping-stones, these should be irregular in outline, and, in fact, providing the upper surface is sufficiently smooth for pleasant tread, the more irregular they are the better.

Stepping-stones are useful, not only for crossing water, but in the low, marshy places in the rock garden, and can even be used with good effect to form the main paths (see illustrations). Stones used for this purpose should be selected, not made, but if any rough dressing has to be done, the marks of the tools should always be effaced. Above all things avoid arranging stepping-stones to go the length of any piece of water. Never make a crossing for the sake of introducing stepping-stones. The accompanying simple plans illustrate the right (G) and wrong (H) positions for their use, which should almost invariably be at the narrowest part of the stream.

PLANS G AND H, SHOWING THE RIGHT AND WRONG WAY TO USE STEPPING-STONES.

STONE STEPS WELL PLACED IN THE ROCK GARDEN.

than ordinary powers of design, totally fail in this one respect. Every stone placed should have a reason for it being in its position. None should be used that is unnecessary, and one is far more likely to obtain satisfactory results from too little rather than too much stone. Where the cultivation of alpmes is the main consideration, every stone should be placed with a slight backward slope, so that the ledge formed by it will catch the water and direct it towards the roots of the plants on that ledge. There should be sufficient soil between the stones for root action of the particular plants to be grown in that position.

Steps and Paths.—A very important feature in the arrangement of the rock garden is the creation of steps and paths. To maintain a perfectly natural appearance, these should be of the same stone as is used in the construction of the rock garden. They should be so arranged that they give the impression of being a continuation of the stratification of the adjoining stone. This is really important, many an otherwise good arrangement being spoiled by the introduction of paths formed of another stone altogether, and used in such a way that while they would make excellent paths through other portions of the garden, they are too obviously artificial for the rock garden. With regard to stepping-stones, these should be irregular in outline, and, in fact, providing the upper surface is sufficiently smooth for pleasant tread, the more irregular they are the better.

Stepping-stones are useful, not only for crossing water, but in the low, marshy places in the rock garden, and can even be used with good effect to form the main paths (see illustrations). Stones used for this purpose should be selected, not made, but if any rough dressing has to be done, the marks of the tools should always be effaced. Above all things avoid arranging stepping-stones to go the length of any piece of water. Never make a crossing for the sake of introducing stepping-stones. The accompanying simple plans illustrate the right (G) and wrong (H) positions for their use, which should almost invariably be at the narrowest part of the stream.

VARIETIES FOR EXHIBITION.

Once to every Man and Nation comes the moment to decide.

In the strife of Faith and Falsehood,
For the good or evil side.

THE Sweet Pea grower has to make his choice of the varieties he intends growing, and when he views the lengthy lists contained in every catalogue he may be pardoned if he quails before the task, for the difficulty is not so much what to select as what to neglect. The National Sweet Pea Society has listed many "too-much-alike varieties," and all exhibitors should avail themselves of this and other exclusive expert knowledge by becoming, for the small annual sum of 5s., members of this society. Some readers may think it superfluous to state that Sweet Peas are known as the Spencer or waved varieties, and the grandiflora or non-waved varieties, yet many are still ignorant of this fact.

In making a selection for exhibition purposes, the grower will be guided largely by the schedules of the shows where he intends competing. Personality also is a potent factor in choosing varieties, for without a true love of the flower no real success is possible; thus, each exhibitor will select the varieties and colours he likes most.

A close study of the varieties since each was introduced enables the following list, arranged according to colour, to be recommended as thoroughly trustworthy; and where two or more are mentioned, the names are given, in the opinion of the writer, in order of merit. Of the novelties offered this present autumn, these twelve are good:

King White (A. Dickson and Sons).—Without doubt the largest white Sweet Pea that has yet appeared; a vigorous grower, producing fine, beautifully-waved blooms, mostly fours, of good stems.

Blue King (Bide).—A Lord Nelson in Spencer form, good grower, carrying nicely-placed flowers (abundance of fours), which stand firm and sunshine well.

New Marquis (Dobbie and Co.).—An improved stock of this much-prized mauve variety, and now the best thing in its class.

Illuminator (Burpee and Dobbie and Co.).—A richer and deeper coloured Edith Taylor, excelling it also in growth and size of flowers. One of the prettiest varieties yet raised.

Sincerity (B. W. Deal).—A deep cerise, brighter than Kathleen, a novelty of the previous year, and it is also an advance in size of flowers, of which it carries plenty of fours. An altogether first-class Sweet Pea.

Blue Picotee (Dobbie and Co.).—A better variety than Mrs. Townsend, having more

substance in the flower. It makes a fine bunch for exhibition purposes.

Phyllis (W. J. Unwin).—An improved Mrs. W. J. Unwin, which, in all probability, it will out from popular favour.

Edith King and Mabel Baccus (W. J. Unwin) will delight all lovers of the Helen Pierce family. Both are vigorous and free, and will please either for the garden or exhibition.

Mrs. M'Ilwrick (Malcolm and Dobbie and Co.).—A bicolor with rosy mauve standard and wings of a deeper tone. A vigorous grower, producing plenty of fours. It is delightful when seen growing under glass.

Wedgewood (A. Dickson and Sons).—A medium blue, superior in size and colour to Flora Norton Spencer.

Anglian Royalty (J. W. King) attracted attention at the Chelsea Show, and lovers of this colour should procure it. It requires to be grown in

Dobbie's Sunproof Crimson and Maud Holmes, scarlet—Dobbie's Scarlet, Red Star and Scarlet Emperor; cream pink (pale)—Gladys Burt, Mrs. H. Dickson and Constance Oliver; cream pink (deep)—Margaret Atlee, Mrs. R. Hallam and Doris Usher; cream flake—May Campbell; blue flake—Loyalty; orange flake—Mrs. W. J. Unwin; lavender—Lavender (George Herbert (Dobbie), R. F. Felton, Moonstone and Asta Ohu Spencer); lilac and pale mauve—Improved Bertrand Deal and Bertha Massey; dark mauve—Mrs. J. C. House and Tennant Spencer; cerise (pale)—Edith Taylor; cerise (deep) Kathleen (Deal); magenta—Mme. Christie; ivory—Lady Knox; maroon and chocolate—King Manocl, Nubian and Red Chief Improved (Bolton); maroon flake—Senator Spencer; puce—Elsie Herbert, Helen Williams and Mrs. C. W. Breamore, Orange shades requiring shading; Orange pink—Edrom Beauty; orange scarlet—Edna Unwin and

STEPPING-STONES LAID AS ADVISED IN PLAN G ON OPPOSITE PAGE.

partial shade, but I did not see this variety growing, hence cannot say further of it.

Quaker Maid (Malcolm and Mrs. Hardcastle Sykes).—It is a large Sweet Pea of good substance, a fine free grower, with flowers having a dove grey standard and blue lavender wings.

Turning to varieties of previous years, in whites we have Etta Dyke, White Queen and Nora Unwin; rose and carnine—Rosabelle and John Ingman; bluish—Agricola and Mrs. Hardcastle Sykes; pink (pale)—Eltrida Pearson; pink (deep)—Hercules, Countess Spencer and Pink Pearl; cream—Dobbie's Cream, Deal's Giant Cream (waved) and Clara Curtis; bicolor—Mrs. Cuthbertson, Mat's Joy, Atterglow and Wenloe Castle; blue (light)—W. P. Wright and Flora Norton Spencer; blue (dark)—Lord Nelson Spencer (Sydenham) and Mrs. G. Charles; crimson—

Thomas Stevenson (Dobbie); salmon—Barbara or Melba; salmon pink—Lady Miller; fancies—Charles Foster, Eric Harvey and Prince George.

Selections of varieties for garden decoration, together with suggestions for colour effect, will be dealt with in a future article. S. M. Crow

RELIABLE LILIES FOR GARDEN CULTIVATION.

THERE are several Oriental Lilies which, while admirably adapted for the conservatory, are by no means equally suitable, by reason of their susceptibility to atmospheric influences, for garden cultivation, such, for example, as nepalense, Lowii, wallichianum and sulphureum, of which, however, the distinctive variety last mentioned sometimes does succeed, as with Mr. Grove at Henley-on-Thames, during an exceptional season of brilliant sunlight, such as we had the rare

privilege of experiencing this year. But this, after all, according to my own experience, is only the exception that vouchsafes the prevailing rule.

One of the most reliable and enduring of all Oriental Lilies is *Lilium monadelphum szovitzianum*, a native of the Mount Caucasus regions and of Northern Persia. I have one noble specimen of this Lily that has flowered in the same sheltered and shady situation for fifteen years, and rarely reaches a height of less than 8 feet, thereby eclipsing its attainments (for so Sir Herbert Maxwell has assured me) at beautiful Moureith, the woods surrounding which residence I can see almost daily from this manse across the spacious Bay of Luce. *L. m. szovitzianum* is one of the loveliest of all Lilies; extremely fascinating is the exquisite citron colour of its pendulous flowers, which have invariably a memorably artistic effect. It is really a much more charming Lily than even the great Himalayan giganteum, which has this disadvantage when compared with *m. szovitzianum*; that it takes an offset at least four or five years to build up its immense flowering bulb. The latter is sometimes—as at Moureith—perpetuated by seeds, but this is an extremely protracted process, making great demands upon the patience of the most earnest and persevering cultivator.

It is gratifying to know that such handsome and comparatively recent introductions as *L. regale* and *L. Sargentii* are as hardy and vigorous as the familiar *L. Brownii* (to which they seem to be somewhat closely affiliated) when grown in the open garden, and they will assuredly be acquisitions if they are even more enduring. But I much regret to say that varieties of this special type have never lasted for more than two years in my garden. One short season has generally proved sufficient for the lifetime, however charming, of *Kramerii* and *rubellum*, whose diminutive bulbs, in our humid Scottish climate, too prematurely disappear, leaving no trace of the bulbous origin of their existence behind.

Speaking from long and patient experience, I would say that the most reliable of all Oriental and Occidental Lilies for garden culture are *auratum*, especially *platyphyllum*, and the attractive forms *Wittii* (almost pure white) and *virgale*; *szovitzianum* and *giganteum*; *candidum*, one of the most graceful and richly fragrant of all Lilies, which should be even more widely cultivated (especially for contrast among beds of pink and crimson Roses, as in Logan Gardens in this county) than it is; the equally odorous *washingtonianum* and the luminous scarlet *Martagon*; *tigrinum splendens*; the various charmingly contrasted varieties of *elegans* or *thundergiantum*; *longiflorum* varieties *Wilsonii* and *giganteum*; *Henryi parviflorum*, *Burbankii* and *speciosum magnificum*.

Wigtownshire N.B. DAVID R. WILLIAMSON.

THE GREENHOUSE. THE WINTER-FLOWERING BEGONIAS.

THESE Begonias are rapidly coming into favour now that their cultural requirements are being more fully understood. They are the result of inter-crossing the pretty *Begonia socotrana*, a pink-flowered species with fibrous roots, with varieties of the tuberous-rooted section, which produce such a gorgeous display during the

rose-carmine tinged with scarlet; *The Gem*, a fine rosy red; *Winter Cheer*, semi-double, rose-carmine; and *Winter Perfection*, semi-double, bright rose-pink. Those of recent introduction embrace *Optima*, a lovely shade of orange-salmon; *Fascinator*, bright salmon; and *Emita*, a fine orange-scarlet.

Of Messrs. Chibran's new kinds I would call attention to *Scarlet Beauty*; *Eclipse*, salmon-scarlet; *Chibran's Crimson*; *Lacy Chibran*, orange suffused with rose; *Altrincham Pink*, apricot orange suffused with pink; *Miss Chibran*, rich bluish pink; *Chibran's Pink*; and *Progress*, salmon and orange, all of which have double or semi-double flowers.

Cultural Hints.—New varieties are obtained from seed, but the amateur and general gardener will increase his stock by the usual method. This is by cuttings, which may be taken any time from April till August. They are made from the young shoots which form in the axils of the leaves after the plants have completed their season of rest. Make them in the usual way by cutting off the lower leaves and severing the stem immediately below a joint. Place them singly in 2½-inch pots, using a sandy compost, and then arrange them in a hand-light or small propagating-trape where the temperature does not fall below 70° Fahr. Directly they have filled their pots with roots, put them into others two sizes larger, and so on till they reach the flowering size. Cuttings that are rooted in the early months will require pots about six inches in diameter, and a later batch will need 1½-inch or 5-inch receptacles. A good rooting medium consists of the best fibrous loam, two-thirds; leaf-mould, one-third; and a little silver sand. The loam should be rather on the light side, and for full-sized plants a sprinkling of well-decayed manure may be incorporated with the mixture. The pots should have one-fourth of their depth filled with drainage, and when repotting do not make the compost too hard.

At this period of the year many of these Begonias will be in flower, and, when these are over, a partial rest should be given until the end of March in a temperature of 55° to 60° Fahr. At this time they need very careful watering; in fact, this may be said to be the most critical part of their existence. But if they are kept moderately dry, no harm will accrue. We should aim at giving just sufficient to maintain the stems and foliage in a healthy condition. After growth commences, the plants will need repotting in the mixture named above, and they ought to be placed in a temperature of 60° or 65° Fahr. As root action becomes vigorous, more water may be given, and at no time must they be allowed to suffer from drought. A somewhat moist atmosphere is essential throughout the growing period, but no overhead spraying is advised, and any condensation of moisture on the leaves is detrimental to their welfare. W. B.

WINTER-FLOWERING BEGONIA OPTIMA. THIS HAS BEAUTIFUL ORANGE SALMON COLOURED FLOWERS.

summer months. Two firms stand out conspicuously in raising these gems, viz., Messrs. J. Veitch and Sons, Limited, Chelsea, and Messrs. Chibran of Altrincham. The former were (as in many other instances) the pioneers, and the first plant they introduced was *John Heal*, named after that veteran hybridist who has served his firm for over fifty years. This was followed by other novelties, such as *Elatior*, a semi-double flower of rich rosy-carmine shade; *Fusion*, also semi-double, light carmine-toned with scarlet; *Ideala*, bright rosy-carmine; *Mrs. Heal*, brilliant

GARDENING FOR BEGINNERS.

HOW TO PROPAGATE CHRYSANTHEMUMS.

THE Chrysanthemum is not a difficult plant to propagate. Indeed, it is one of the easiest, and the majority of the varieties produce cuttings very freely. Although it is a simple matter to increase the stock, or to renew it by means of cuttings, the best results are only obtained when these are carefully

from the stems of the old plants. The first named must always be used, if obtainable; the second and third kinds where new varieties and others that are very shy in producing cuttings are concerned. It is, however, much the wisest plan to purchase cuttings, if this can be done. Even in the case of strong cuttings, some from a distance would thrive better than old stock that has been propagated from for a number of years.

It is advisable to propagate some cuttings later—in January and February—and when this course is decided upon, select the strong suckers, remove all weakly ones, and so strengthen the former for use in due time. Now, towards the end of December the cultivator must make a selection of the varieties he intends to propagate. They will be, first, those that are late flowering, followed by the medium early, the earliest of all being inserted at a later date. Late-flowering sorts should be allowed a long period of growth, as they are naturally late in making the first break, and also in producing the crown bud that is usually "taken."

Soil for Cuttings.—Use the very best procurable, as it must remain round the roots throughout the growing season. There can be no better compost than one made of fibrous loam and leaf-soil in equal proportions for the strong-growing variety and rather more leaf-soil than loam for the weak-growing ones. Plenty of coarse sand must be added in every case.

The Sketches explained.—Fig. A, No. 1, shows a good, free-growing cutting, the stem of which must be severed just below a joint with a sharp knife. No. 2 represents a bad cutting with a flower-bud in the point of growth. No. 3 shows a rooted sucker; the rooted portion must not be inserted; cut off the stem as denoted by the dark line. No. 4 depicts a good cutting prepared for insertion. If a cutting is severed between the joints, it will decay, as shown at No. 5. No. 6 represents a cutting bearing buds; if topped, this kind usually produces more buds, as shown at No. 7.

In Fig. B, No. 1 shows how to insert cuttings round the side of a pot; No. 2, the callus forming; No. 3, the new roots; No. 4, a cutting inserted singly in a pot; No. 5, cuttings in a small frame on a greenhouse stage; and No. 6, cuttings in pots in a cold frame. Water with care at all times, and ventilate a little every day. G. G.

A.—CHRYSANTHEMUM SHOOTS SUITABLE AND UNSUITABLE FOR CUTTINGS, AND HOW TO PREPARE THE GOOD ONES FOR PLANTING.

treated, rooted under the best conditions, and cared for afterwards as they require more rooting space and head-room. Amateur cultivators may succeed in striking 90 per cent. of all cuttings inserted if they possess an ordinary garden frame, and 95 per cent. if they can make use of a greenhouse. In the unheated frame there is much moisture to contend with during the months of December, January and February. From a greenhouse only slightly heated, all excessive moisture can be expelled. Preference should, therefore, be given to propagation on a greenhouse stage, if both frame and stage are available.

Good and Bad Cuttings.—There are three qualities in cuttings to be found every year, namely: Suckers growing from the soil in the old pots without buds prematurely formed; suckers possessing flower-buds; and young shoots growing

following will get the full benefit from the enriched soil. It is only necessary to keep the manure in an open shed, or to cover it sufficiently to prevent water passing through. SHAMROCK.

HINTS ON STORING DAHLIAS.

AFTER lifting, Dahlia tubers should be well dried before storing. For those possessing ample suitable accommodation, the actual storing presents but little difficulty; but there are many not so fortunately situated, and who hardly know how to preserve the tubers through the winter. This latter class of gardeners should give the storing in clamps a trial, for when this is rightly done the tubers winter well and later grow satisfactorily. Choose a dry site for the clamp, raise the tubers from direct contact with the ground surface by, first, a few thorns or a splined platform—in other case well covered with dry Wheaten straw—and, having arranged the tubers pyramid fashion, cover well with enough dry straw

B.—HOW TO PLANT THE CUTTINGS AND THEIR SUBSEQUENT TREATMENT IN GREENHOUSE OR FRAME.

HINTS ON MANURING SOILS.

WHEN winter comes, the thoughts of the cultivator turn to the question of manuring, especially in the case of the application of manure to the vegetable ground. Experienced cultivators use their judgment and only apply manure to heavy soils now, reserving manures for light land until the spring. When organic manures are kept for several months, during the winter season they should be protected from all rains, as, if exposed in large or small heaps, the greater portion of the plant food would be washed away, and the better course to take would be to bury it, even in the light ground. Heavy, retentive soils may be manured now, and, indeed, in dry weather at any time during the winter; but light soils must not be manured before the months of February and March. Then the crops

to preserve them from frost. Now cover the whole well with earth, as when clamping Potatoes, leaving a wisp of straw projecting at the centre to ensure ventilation, and then thatch the clamp securely. The result will rarely fail to please, and will solve the storing difficulty. J. T. B.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Pleasure Grounds.

Rhododendrons.—Established beds of Rhododendrons are very much benefited by a top-dressing of old spent hot-bed manure, or even leaf-mould. These being surface-rooting plants, it is not wise to fork over the beds. Such a top-dressing will keep the plants in a good vigorous condition, with the foliage green and more or less erect, according to the variety. Starved plants, even in the winter, are yellow in appearance, the foliage looking as though it is flagging.

Hardy Azaleas are also greatly benefited by a mulch of this description. Then, again, the colour and size of the bloom are much enhanced, while the foliage is larger and brighter.

Flowering Shrubs.—The extreme mildness of the winter has much to answer for. Here in these gardens we have had several varieties of the shrubby *Spiraea* in bloom during November and December, while *Berberis Darwinii*, in several instances, has given a full crop of bloom. *B. stenophylla* is not so precocious, only isolated shoots having opened their blooms; but so forward are the buds that one is greatly concerned as to the amount of damage that a hard frost will do, and certainly it does not augur well for a good show of blossom in the spring.

The Flower Garden.

Bedding Geraniums.—Where these are rooted in boxes or several in a pot, it may be advisable to get them potted off singly as soon as possible, as they have made a good deal of growth this autumn and, being close together, there is danger of their becoming unduly drawn. It may be argued that it is early for this operation, and so it is; but it is better to do it now, when, perhaps, there is more time, than to leave it till February, when work is generally more pressing.

Pelargonium Maxime Kovalevsky.—This somewhat new orange scarlet variety should prove effective for bedding if it is floriferous enough. I have seen two or three beds of this variety, and in each instance it was perfectly satisfactory. Not having used it for bedding purposes, I cannot definitely state that it is a good continuous bloomer, but hope to prove it during 1914.

Plants Under Glass.

Liliums in variety that are being forwarded for Christmas should have the stamens removed as they open—this to keep the flowers clean; and wherever possible the plants should be removed as the flowers open to a cooler house to keep them in good condition as long as possible.

Lachenalias.—Although these plants do not like forcing in any way, those that are in frames may with advantage be removed to a light, airy house. If left in frames too long, the foliage gets big and soft. The drier atmospheric conditions prevailing in a house hardens the foliage, and the plants when in bloom have a much better appearance.

Freelias.—For the same reason *Freelias* are much better in a cool house. Plants that are well rooted may be given liquid animal manure whenever they are dry, this being preferable to artificial manure, and it will tend to increase the size of the blooms.

Humea elegans.—This subject requires very careful cultivation, especially during the winter months. The plants must at no time be allowed to get dry, as this is fatal to the foliage. Potting on also must be done before the roots become too densely matted together in the pots, and if in 4½-inch or 6-inch pots, the next shift should be into their flowering pots—8½-inch being a very suitable size, though if the plants are wanted for use in small groups, a few should be left in fairly small pots, or they will grow too large.

The Kitchen Garden.

Forcing Frames that are not in use should, if possible, be overhauled and painted, but do not make the mistake of using any of the tar preparations as a preventive of rot. The fumes that arise from them will prove a nuisance for months. Lettuce, Beans, Radishes, &c., all being burnt by them every time the sun comes out at all powerful, even though there may be plenty of air on the frames at the time.

During **Wet Weather** lights may be scrubbed, large labels made and painted, and stakes sharpened and arranged in different lengths for the various purposes for which they may be required.

The Root Shed also should be looked over as the opportunity offers, removing any subjects that show the slightest evidence of decay. Late Potatoes that may have been put away in bulk should certainly be gone over, selecting any that may be required for seed, while the really small ones should be given to the pigs or poultry after being boiled.

Rhubarb.—Further supplies should be put in the forcing-house, as with the turn of the year Apples and stewing Pears will be scarcer, and Rhubarb is always welcomed in the kitchen as a change.

Lettuce and Cauliflower.—Seeds may now be sown for early crops in frames. Of the former, *Golden Ball*, *Tom Thumb* and *All the Year Round* are the best varieties in the order named; while for Cauliflowers I have found *Carter's Forerunner* as good as any.

Tomatoes.—A sowing of Tomatoes should also be made to succeed those sown or propagated from cuttings in the autumn. Sow thinly and keep very near the glass, or the seedlings will soon become attenuated at this season. The smaller varieties of Tomatoes are best for early work, the variety *Sunrise* being excellent.

The Hardy Fruit Garden.

Pruning.—This should be continued as the weather permits. Having made an early start, it gives one a chance to select or choose the more favourable days for pushing on with the work. *Pyramid* and bush trained Apples and Pears cannot well be kept too open, and wherever possible the branches should be about two feet apart, thus allowing a maximum of light and air between them. In very many instances, even in otherwise well-kept gardens, enough attention is not paid to this matter, and were the pruning-saw used rather more, better results would often be obtained in some of the older, and consequently larger trees.

THOMAS STEVENSON.

(Head-gardener to E. Mocatta, Esq.)

Woburn Place Gardens, Addlestone, Surrey.

FOR NORTHERN GARDENS.

The Flower Garden.

Top-Dressing.—There are various perennials which, when grown in beds or masses of any kind, are benefited by an annual top-dressing. *Lily of the Valley* is one of these, for unless liberally cultivated, good spikes and large blooms cannot be obtained. From 2 inches to 3 inches of spent hot-bed or Mushroom manure makes an excellent top-dressing either for *Lily of the Valley* or for *Daffodil* beds, especially the commoner varieties, where they are grown in masses for cutting. *Dog's-tooth Violets*, *Scillas* and *Grape Hyacinths* should receive about an inch of maiden loam; failing this, old potting soil, with a little manure such as I have just indicated. Varieties of *Primula Sieboldii* should also have a similar top-dressing, but only just deep enough to cover the fleshy rhizomes.

Marking Bulbous Plants.—Where valuable bulbous plants are interspersed among the general run of hardy border flowers, it is often difficult to locate them when wanted, some of them ripening their foliage early in the summer, while others have not begun to push when the beds or borders are being forked or dug over in the spring. To obviate the difficulty I have found it a good plan to insert a green-painted hard-wood peg about an inch thick at each plant or clump. A stock of these pegs could be made and painted during bad weather, to be ready for use when growth commences in the spring. Oak or Ash is very suitable for this purpose.

The Rock Garden.

The Beginner's Selection.—Those who are commencing rock gardening on a moderate scale, and are undecided as to what to order for early

spring planting, will be well advised not to be too ambitious at the start, or disappointments are sure to follow. Commence with things that succeed with ordinary cultivation. One can never be far wrong with a good selection of *Campanulas*, *Phloxes*, *Primulas* (for the lower reaches), *Saxifrages*, *Dianthus*, *Myosotis rupicola*, *Aubrietias*, *Lithospermum prostratum*, *Saponaria ceymoides*, *Veronicas* and *Viola gracilis*. I would also include that gem *Daphne blagayana*, which, unlike any of the foregoing, requires stony peat. All the others indicated will thrive in either rich or light loam.

The Pleasure Grounds.

Clothing Tree Stumps.—Where trees have been cut down to the ground and the process of grubbing out the roots is considered rather troublesome, the stumps can be mounded over with soil and then planted with some of the Mossy *Saxifrages* or *Sedums*.

Summer-Houses.—Those intending to invest in a summer-house have great choice. There is the ready-made, portable, revolving type; also the substantial and durable type covered with rustic work of Larch, Spruce or Oak. During this autumn I revisited one in Aberdeenshire which I have known for half a century. Inside it is done in rustic work with split Hazel. It has been revarnished from time to time, and it looks as fresh to-day as it did fifty years ago. Much, however, can be said in favour of the inexpensive plain wood in summer-houses, covered with natural climbing plants, *Honeysuckle*, *Hops*, *Clematises*, *Roses* and other quick-growing plants.

Plants Under Glass.

The Chrysanthemum Order.—Those who intend purchasing new varieties should place their orders without delay. A perusal of the trade lists will show that the singles are now in the ascendant, and I will confine myself to suggesting a few varieties of these which are well worth growing: *Ceddie White*, chestnut, with gold centre; *Ivor Grant*, rose pink, with white zone; *Josephine*, golden yellow; *Manor House Terra Cotta*; *Mensa*, white; *Golden Mensa*; *Mrs. Lou Thomson*, a primrose sport from *Mensa*; *Sylvia Slade*, rosy garnet, with white band round the disc; and *Red Chief*, chestnut. *Ceddie White* makes lovely sprays, but all the other varieties indicated had better be disbudded.

Christmas Decorations.—The extent and character of these must depend upon the size of the rooms, the taste of the owner, and the quantity of material available. Evergreens, Holly and Ivy are always useful. Berried plants are generally acceptable. *Solanums*, *Rivina humilis*, *Cratægus Pyracantha*, *Cotoneaster microphylla*, *C. Simonsi* and *Skimmia japonica* are all eligible. White flowers, too, are always in good taste, and should include *Roman* and other white *Hyacinths*, *Paper-White Narcissus*, *Lilium Harrison* and *Lily of the Valley*. Simplicity should be the aim of the decorator. A trail of Ivy twined naturally round the stem of a tall reading lamp cannot be improved upon, nor can a sprig of berried Holly in the hand of a statuette.

Fruits Under Glass.

Potting Off Early Tomatoes.—Where Tomato seed was sown last month for early use, the seedlings will now be fit for potting off, and care must be taken with the seedlings, or damping off is likely to ensue. Use 2½-inch pots and employ a fairly sandy loam without any fertiliser. Instead of placing the plant in the centre of the pot, put it on one side, and this will reduce the risk of damping off. Place the plants in as light a position as possible, with a temperature of about 55°, and water rather sparingly. Retain the surplus plants for a time, lest damping off should take place.

The Vegetable Garden.

Top-Dressing Mint.—Mint is a very exhausting crop, and should receive a good, rich top-dressing annually. The early spring is perhaps the ideal time for this; but a hundred things require attention then, and it can be done now with advantage.

Greens.—Do not throw away the stems when the plants have been cut over; they will yield a second crop in the spring.

CHARLES COMFORD.

Broomfield Gardens, Davidson's Mans, Midlothian.

GARDENING ACROSTICS.

AS announced in our issue for November 22, we are publishing eight gardening acrostics, to be divided into two sets of four each. Each light correctly guessed will count one, and also each "first" and each "last." Thus, supposing the whole is China (firsts), Aster (lasts), the four marks will be seven—one for China, one for Aster, and one for each of the five lights C . . . A, H . . . S, I . . . T, N . . . E and A . . . R. Hence, suppose a competitor got everything right but the light I . . . T, he would count six, and it would not matter if he attempted to solve that particular light or not.

Those entering for the acrostics must observe the rules published on page 607 of the issue for December 6.

DOUBLE ACROSTIC No. 3.

Firsts—One of the oldest artificial forms of gardening. Matius introduced me into Rome.

Lasts—The very latest absurdity of our neighbours across the Channel.

1. The author of these lines:

"How well the skilful gardener drew
Of flowers, and herbs, this dial new;
Where from above the mulder sun
Does through a fragrant zodiac run,
And as it works, the industrious bee
Computes its time as well as we!
How could such sweet and wholesome hours
Be reckoned but with herbs and flowers."

2. The surname of the man who first wrote an English book on flowers, not in the "herbal" style.

3. A mysterious disease, so affecting the leaves of certain trees as to suggest its name.

4. A chorister and courtier, a farmer and poet, from whom we get many pre-Gerardian hints about English gardens.

5. A species of Tree Mallow known to Abercrombie, but which only last year received an award of merit.

6. A Pear of Shakespeare's day, possibly introduced by Leland.

7. Devil's Dye.

8. I am half covered with a cupula.

9. The Swan River Everlasting.

10. Stored up by the Dahlia.

11. A special *bête noire* of Repton's.

Solutions of the above must be sent so as to reach the Editor at 20, Tavistock Street, Covent Garden, London, W.C., not later than the first post on Saturday, December 27. Mark the envelope "Acrostic" in the top left-hand corner.

SOLUTION AND NOTES OF DOUBLE ACROSTIC No. 1.

CLIMBER—TENDRIL.

- * 1. C AS T
- † 2. L ETTUC E
- ‡ 3. I XIOLIRIO N
- § 4. M AUN D
- || 5. B AKE R
- ¶ 6. E ICHLER I
- ** 7. R UNCIVAL L

* Flower-pots are usually sold by the "cast"—sixty small 3-inch pots go to a cast. † See "History of Cultivated Vegetables," second edition, Vol. I., pages 316 and 317, by H. Phillips. ‡ The *Ixiolirion tataricum* is probably hardy in light, sandy soils; it has lovely blue flowers, which remind people of Freesias; they last well in water. § The quotation is from Mrs. Earle's "Pot-pourri

in a Surrey Garden." || J. G. Baker of Kew. ¶ *Eichleri* is one of the best of the newer "species" Tulips for garden decoration; see *Botanical Magazine*, plate 6191. ** Tusser, who wrote "Five Hundred Pointes of Good Husbandrie," thus speaks of the runcival pea: "Dig garden, stroy mallow, now may ye at ease, And set (as a dainte) thy runcivall pease." —Quoted in "History of Gardening in England," third edition, page 80.

RESULT OF ACROSTIC No. 1.

In accordance with our rules, it was possible for competitors to get nine marks for this acrostic, one for each of the seven lights and one for each correct "first" or "last." The following marks have been awarded:

Nine marks.—"W. R. D.," "Elm," R. Chapman, "White Lady," "Hero" and L. A. Loudon.

Eight marks.—"Mona," "Nautilus," "Jan," G. Tolson, "Pmg," "Erbel," "Rusticus," "Judith," "Penwarne," "Westbank," "Shelah" and "Tortoise."

Seven marks.—"Iris," "Tempus Fugit," "E. C. E.," "Miss Marindin," Mrs. Devenish "Miller" and "Boarsvale."

Six marks.—"Anna Olivier" and William Slocombe.

Five marks.—"St. Kevins," "Mowgli," G. D. King and "P. P."

Four marks.—A. Henderson.

Two marks.—"Teutamien," M. Browne, Wm. Acwalt and G. B. Bassett.

One mark.—"Glevum."

OBITUARY.

MARTIN JOHN SUTTON.

It is with deep regret that we have to record the death, in his sixty-fourth year, of Mr. Martin J.

THE LATE MARTIN JOHN SUTTON.
(Photo Elliott and Fry.)

Sutton, J.P., which occurred suddenly on Sunday last at the Piccadilly Hotel, London. He was the head of the famous Reading firm, and had been staying in London for the Smithfield Club Show, of which he was a vice-president. An anæsthetic had been administered to him for a dental operation, and death ensued. Mr. Sutton was the eldest son of the late Mr. Martin Hope Sutton, who, with his brother, Alroy, founded the seed establishment at Reading. He entered the business at the age of sixteen, and in 1871, when he came of age, was taken into partnership by his father and uncle. In 1887 he became head of the firm, and continued so until his death. It was in agricultural circles that Mr. Sutton was most widely known. For nearly a quarter of a century he was a leading member of the Royal Agricultural Society, while he was connected with various other societies, including the Bath and West Society, the Royal Counties Society and the Smithfield Club. Mr. Sutton was much appreciated as a writer on agricultural subjects, his best-known work being "Permanent and Temporary Pastures." To the end he continued to supervise actively the business of the firm, and only a few months ago, in conjunction with his brothers and sons, he conducted the negotiations, so important in the horticultural world, in taking over Messrs. Veitch's seed business and the nursery at Langley, Slough. Mr. Sutton was a great philanthropist, being a generous subscriber to religious, social and other clubs. He was a Knight of Grace of the Order of the Hospital of St. John of Jerusalem in England and a Chevalier of the Legion of Honour. He resided at Wargrave Manor, Berkshire, and was a Justice of the Peace for Reading and for Oxfordshire, a member of the Berkshire County Council, and Mayor of Reading in 1904. Mr. Sutton was twice married, his second marriage taking place in 1912. There are two sons and a daughter by the first marriage, the latter being the wife of the Vicar of Wargrave.

JOHN PEARSON.

MR. JOHN PEARSON, the gardener at Beechwood, Murrayfield, Edinburgh, died on December 10, and many will receive the news of his death with regret. Mr. Pearson was in his seventieth year, and was much respected for his character and for his ability as a gardener.

ANSWERS TO CORRESPONDENTS.

THE GREENHOUSE.

ARUM LILIES GONE WRONG (Reader).—If the plants were healthy before, we should say that the cause of the leaves being discoloured and turning yellow must be found in the soil or in the water given them. Have you used artificial manures too freely, or have you given too much soot?

BEGONIA GLOIRE DE SCEAUX (W. H.).—This *Begonia* was raised by MM. Thibault et Keteleer of Sceaux in France, and distributed by them in 1885. By the raisers it was announced as a hybrid between *Begonia socotrana* and *B. sub-peltata*, but doubts have before now been expressed as to whether *B. socotrana* had any part in its origin. At all events, no further information on the point can be gained. It is indeed a beautiful *Begonia*, regarded either from a flowering or foliage point of view.

ADVICE ABOUT A GREENHOUSE (N. B. L.).—The amount of ventilation required in the greenhouse will to a certain extent depend upon the class of plants you intend to grow therein. It is, however, a good plan to ensure ample ventilation, and the ventilators not required may be kept closed. Of course, the main ventilation will be at the apex of the roof, and may be arranged in various ways. If the house has a lantern on the top, the side of the lantern may be hinged on the upper part and open at the bottom by means of a ratchet acting on all the ventilators at the same time. This is, of course,

the most expensive system of all, but decidedly the best. Another plan, if there is no lantern, is to have hinged lights along the top, extending the whole length of the house, but disposed alternately. These should be so arranged as to allow of the opening being 15 inches in depth. This will be enough roof ventilation, even on a hot day. Besides this, three traps should be worked in each of the side walls at about half their height. These traps, if 18 inches long and 8 inches or 9 inches wide, will be extremely useful for opening, especially in bad weather. The height of the central stage will, of course, depend upon the plants that are intended to stand thereon, but 3 feet would for general purposes be a very good height.

TREATMENT OF CLIVIAS (*Anriety*).—The Clivias that have been outside during the summer should be wintered in a greenhouse in which a minimum night temperature of 45° to 48° is maintained. They should, during the winter, be kept on what is usually termed the "dry" side, that is to say, enough water must be given to keep the soil moderately moist, but on no account must they be watered till they absolutely require it. Clivias flower, as a rule, during the spring months, but one or two uncommon kinds bloom in autumn and winter. If the roots are in good condition, the plants will stand for three or four years without repotting, and keep in good health even if they are pot-bound. A 10-inch pot should be sufficient for a large specimen. If repotting is necessary, it must be done immediately after flowering, using a compost made up principally of fibrous loam, with a little leaf-mould and sand, and, if available, some small nodules of charcoal. Throughout the summer the plants may be watered somewhat liberally, but the newly-potted ones will not require so much water as those that are established. These last may, when growing, be assisted with an occasional stimulant, either one of the many plant foods now on the market or a mixture of liquid manure and soot-water combined. In any case, as with all plants that have thick fleshy roots, only a weak dose of stimulant must be given, otherwise the roots may be injured.

MISCELLANEOUS.

SHRUB FOR A LOW PORCH (*R. W. R.*).—You will find *Berberidopsis corallina* a suitable climber for the position indicated. It is a native of Chili, and bears a profusion of showy, coral red blossoms. It has also the merit of being evergreen.

MILLIPEDES (*H. A. F.*).—The little pests you send are millipedes. They are extremely troublesome pests, and very difficult to eradicate. They feed on all sorts of fleshy roots and even large seeds, and do enormous damage. Lining the soil is the best method of dealing with them, but where plants are growing this cannot be easily done, and it would be well to bury pieces of Potato or Carrot, marking the places with sticks, and examine and remove the captures every few days, dropping them into paraffin or boiling water.

PLASTER OF PARIS AS A MANURE (*E. L. E.*).—You may certainly use the plaster of Paris mentioned in the way you suggest. Plaster of Paris is sulphate of lime or gypsum from which the water of crystallisation has been expelled, and which takes up water when it is able to get it again and sets in a hard mass. If this mass be ground again to a powder, it is practically the same as sulphate of lime, and may be added to soil for the same purpose as that substance is used. The sulphate is not quite so good in counteracting acidity of the soil as are some of the other forms of lime, but at the same time it has a very beneficial effect upon the soil, and both clays and sands are made more productive by its use.

NAMES OF PLANTS.—*W. E. P.*—1, *Solanum jasminoides*; 2, *Coronilla Emerns*; 3, *Neprolepis cordifolia*; 4, *Campanula isophylla*.—*C. S. S. J.*, *Edinburgh*.—1, *Thyrus Serpyllium lanuginosus*; 2, *Saxifraga cuneifolia*; 3, *Veronica elliptica*; 4, *Lonicera* species, cannot name without flowers; 5, *Erysimum rufestris*; 6, *Tolmiea Menziesii*; 7, cannot name without flowers; 8, *Erigeron alpinus* variety; 9, *Claytonia sibirica* (probably); 10, *Sedum praealtum*; 11, *Sciazinella krasnsiana*; 12, *Tradescantia crassifolia*.

SOCIETIES.

THE NATIONAL ROSE SOCIETY.

The annual general meeting of the above society was held at the Westminster Palace Hotel, Victoria Street, Westminster, on Thursday, the 11th inst. Mr. C. E. Shea, the president, was in the chair, and a large number of members were present. After the minutes of the previous meeting had been taken as read, scrutineers of the ballot were appointed, these being Messrs. C. C. Williams and H. E. Mount. Before commencing to read the report of the Council for 1913, Mr. E. Mawley, V.M.H., the hon. secretary, read a telegram from Mr. E. T. Cook, president of the Rose Society of Canada, conveying good wishes from the Canadian Society to the National Rose Society. The following are the salient points of the report:

"During the past twelve months, with one exception, more new members have joined the society than in any previous year. For the first time in the history of the society the number of members exceeds six thousand.

In order to encourage growing Roses under glass, a new departure this year was made by holding a spring show in the Royal Horticultural Hall, Westminster, on May 1. Considering it was the first exhibition of the kind ever held in this country, and that the cold and sunless weather somewhat upset the grower's calculations as to the date, it must be regarded as having been, on the whole,

a success, and judging from the interest displayed by the members and their friends in the exhibits, this spring Rose show of the society promises to become an extremely helpful and popular exhibition.

The metropolitan show again took place, by the kind permission of the President and Council of the Royal Botanic Society, in their beautiful gardens in Regent's Park, the date of the exhibition being July 4. Favoured by the season and the weather on and before the show day, this proved the largest and finest exhibition the society has ever held. The attendance of members and their friends was also larger than on any previous occasion.

The provincial show took place at Gloucester on July 15. This, too, was a fine and extensive exhibition; indeed, larger than either of the three previous provincial shows. The arrangements for the exhibition were excellent, and admirably carried out by the hon. secretary, Mr. W. H. Pickford, assisted by other members of the local committee.

The autumn exhibition, which was held in the Royal Horticultural Hall, Westminster, on September 11 and 12, proved one of the smallest and least attractive shows of the kind the society has yet held. This was, no doubt, owing to the dry and otherwise unfavourable character of the weather, so far as Roses were concerned, during the summer and early autumn of this year.

During the past year the 'Rose Annual for 1913,' containing for the first time some coloured illustrations, was distributed to the members in April, while a new edition of the 'Official Catalogue of Roses' was sent out in November.

At the last annual general meeting the Dean Hole Memorial Medal was awarded to Mr. George Dickson of Newtownards, County Down, Ireland, for the great services he has rendered to the Rose during the past half century in raising so many new Roses of special merit, and as one of the most successful pioneers in the scientific hybridisation of Roses.

The number of societies in affiliation with the National Rose Society is now fifty-five, or about the same as in the previous year.

The Council record, with regret, the death in January last of Mr. Alfred Tate, since 1904 a vice-president of the society, and a keen rosarian. His Rose garden at Leatherhead was the largest and finest in the kingdom, and his exhibits of decorative Roses were the best ever staged by an amateur. He was regarded with the highest esteem by all who knew him.

They also regret to announce the death in October last of Mr. J. T. Strange, whose genial nature endeared him to all with whom he came in contact in the Rose world. He was one of the society's oldest members, having joined the National Rose Society in 1877, when he was at once elected on the Council, and last year he became a vice-president of the society.

Judging by the amount received in gate-money from the general public at the exhibition in the Royal Botanic Gardens there was a good attendance of visitors. The receipts from all sources during the past year, including a balance from the previous year of £442 12s. 2d., amounted to £4,061 6s. 5d., and the expenditure to £3,586 10s. 6d., leaving a balance at the bankers of £474 15s. 11d., after £500 had been placed to the reserve fund, which now stands at £2,000.

During the past year 1,045 new members have joined the society, or a greater number than in any previous year except 1910, when the number of new members was 1,050. Allowing for the losses by death and resignation, the total number of members is now 6,035. Taking the year as a whole, nearly three new members a day have been added to the list of membership.

The spring show will take place in the Royal Horticultural Hall, Vincent Square, Westminster, on St. George's Day, Thursday, April 23.

The metropolitan exhibition will be held in the Royal Botanic Gardens, Regent's Park, on Tuesday, July 7.

The provincial exhibition will take place, at the invitation of the Mayor and Corporation of Bath, in the Sydney Gardens of that city on Thursday, July 16.

The autumn exhibition will be held in the Royal Horticultural Hall, Vincent Square, Westminster, on Thursday, September 24.

The financial statement was next read by the hon. treasurer Mr. G. W. Cook.

The president, in proposing the adoption of the report and financial statement, welcomed the ladies who were present, and drew attention to the fact that the year had been one of records and the most satisfactory in the annals of the society. They had put by the biggest sum by £200 than they had ever put on deposit before. The literature sent out had been better than ever. There was still more and better to come, so that members would get more than value for their money. The proposition was seconded by Mr. Frank Cant. In doing so, he said the balance sheet spoke for itself. He thought the distribution of useful literature was one of the wisest steps the Council ever took.

Mr. Lewis Pawle said he thought it was unwise to keep investing in Consols. Mr. Johnson said he would like to see ladies on the Council. He criticised the methods of voting. That afternoon one hundred or so members had elected the Council. All the county members were disfranchised. He would like a postal vote. Mr. W. J. Grant supported this. Mr. E. J. Holland spoke against the postal vote, and also said that it was quite open for ladies to be put on the Council if members would take the trouble to nominate them. The report and financial statement were, after other friendly discussion, carried unanimously.

The chairman then proposed that an honorarium of £150 be granted Mr. Mawley as an appreciation of his services. This was seconded by Mr. G. W. Cook. Mr. Mawley had done, and was still doing, a vast amount of valuable work for the society, and they could well afford

to increase his honorarium from £100 to £150. This was unanimously agreed to with acclamation. Mr. Mawley, in responding, said the most difficult nut he ever had to crack was to express his appreciation of what had been said.

The next business was the alteration of certain rules and by-laws, full particulars of which had been sent to every member. Only one of these, viz., By-law No. 7, gave rise to any appreciable discussion. The proposed alterations in this by-law were for the purpose of more clearly defining what is meant by an amateur, and we publish this herewith, the alterations being in italics: "By the word nurseryman is understood a person who maintains a garden, or other horticultural establishment, for the purpose of returning him a profit. By the word amateur is understood a person who maintains a garden with a view to his own use and enjoyment, and not for the purpose of gaining a profit. No person shall be allowed to compete as an amateur who sells Rose plants, Rose blooms, or buds for budding. As exceptions to the foregoing (a) an amateur may sell his Rose plants when giving up possession of the garden or place where they have been grown, and (b) an amateur may sell new seedlings or sports of his own raising, but only to nurserymen. No person shall be allowed to compete as an amateur who is a resident member of a household where a nursery business is carried on, nor any person who issues a catalogue or price list of Roses, buds for budding, or other horticultural produce. No lady may exhibit as an amateur who is engaged in the floral or horticultural trade, or who is herself a paid gardener, or paid floral decorator, or who is a resident member of the family of one engaged in such trade or employment. Any objection raised as to the rightful qualification of an exhibitor shall be referred to the Council for arbitration, and their decision shall be final and binding on all parties."

Dr. Waddell, the Rev. J. H. Pemberton and one or two others protested against the proposed alterations, on the grounds that amateurs who raised new seedlings were deprived from recuperating themselves financially to the fullest extent. It was to the amateur that they must look for new breaks in seedling Roses, and the National Rose Society ought to encourage amateurs instead of putting obstacles in their way. After a good deal of discussion the proposed alterations were carried by a large majority. The ballot for election of members of the Council resulted in all the proposed members being elected with the exception of Mr. R. F. Felton.

After the meeting a conversation was held, when light refreshments were served, or, rather, scrambled for, to the accompaniment of delightful music. We would suggest that the Council another year hold this pleasant gathering at the Albert Hall or some other large building, so that the large number of members and friends can meet in comfort.

Proposed Edinburgh Winter Garden.

For a considerable time a proposal to erect a winter garden in the West Princes Street Gardens, Edinburgh, has been under the consideration of the Town Council, and several schemes have had much attention paid to them. The proposals were decidedly advanced at a meeting of the sub-committee appointed for the purpose of considering the matter on December 11, when it was unanimously agreed to recommend to the Lord Provost's Committee, which has charge of the consideration of the subject, that a winter garden be erected. Should the committee accept the scheme, and should it be agreed to by the Town Council, the City of Edinburgh would be in possession of a structure which would be a source of much advantage and enjoyment not only to the citizens, but also to the many visitors. At present the latter have few public places in which to shelter in inclement weather, except the somewhat dreary expanse of the Waverley Market under its ordinary conditions. The scheme, which has been prepared by Mr. J. W. McHattie, the Parks Superintendent, and Mr. J. A. Williamson, City Superintendent of Works, is estimated to cost about ten thousand pounds. It provides for the erection of a winter garden composed of stonework and steel, and situated at the east end of the West Princes Street Gardens, next the Mound, and in what is at present about the least attractive part of these gardens. The building would provide seating accommodation for a large number of persons, with suitable provision for plants, together with promenades decorated with flowers and plants. The plans appear to be excellent in conception and in design.

EDITORIAL NOTICES.

Every department of horticulture is represented in **THE GARDEN**, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in **THE GARDEN** will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

NOTES OF THE WEEK.

Votes for Gardeners' Royal Benevolent Institution.—We shall be glad if any readers who have votes to spare will kindly send us their signed voting papers. We are interested in a thoroughly deserving case, and the votes will be utilised to the best advantage.

Burning Garden Rubbish.—It is a good plan, where it is possible, to keep a smouldering heap going, particularly through the winter, so that all tree or bush prunings and other dead material that is cut from the beds and borders, as well as weeds when they are not too wet, may be burnt. The ashes are excellent manure for most crops, but should be kept in a heap until they are required, for if scattered about they lose much of their valuable properties.

Preparing to Plant Bush Fruits.—Those intending to plant Gooseberries or Currants in early spring should lose no time in preparing the ground for their reception. The ground should be bastard-trenched and receive a good dressing of organic manure, to be incorporated with the top spit. If the soil is light, cow-manure will be most suitable; but if the ground is heavy, stable manure will be best. Add a little wood-ashes if available. Lime can be applied and raked in after planting in spring.

General Index to this Volume.—As the present issue completes Vol. LXXVII, we are presenting a general index, together with a title-page and frontispiece suitable for binding the whole of the numbers published during the present year. Next week we shall publish our Special New Year Number, which will be considerably enlarged and contain many new and interesting features. We take this opportunity of thanking those of our readers who have sent us seasonable greetings, which are heartily reciprocated.

Grass Orchards.—These are perhaps not so much in evidence as they once were. Nothing, however, can be said against the system if judiciously carried out. One thing has been abundantly proved, viz., that if the best results are to be obtained, a circle of 6 feet to 8 feet in diameter must be cultivated round each tree. Those, therefore, who have hitherto allowed the grass to grow right up to the stem of the tree will do well to scarry round it for the distance indicated above, and then fork in some rotten manure and bone-meal.

The Treatment of Early Bulbs.—Many varieties of early Tulips, Narcissi and Hyacinths should be introduced into heat for blooming early in the year. Those that are pushing up their flowers must be carefully handled to get the best results, maintaining a fair amount of heat and moisture where they are being forced, so as to get as good a stem on them as possible. Although not always admired, the Duc van Thol varieties of Tulips

are useful during the Christmas season, particularly as there will be a shortage of flowers during the next two or three weeks. Owing to the Chrysanthemums being much earlier than usual, all other kinds of bloom will be in demand.

Streak Disease of Sweet Peas.—The National Sweet Pea Society, with the object of securing a preventive and cure of the disease known as streak, are offering a prize of ten guineas and the gold medal of the society to the first person who can prove to the satisfaction of the committee that he or she has a cure. As arrangements are now being made for testing preventives or remedies, anyone who has discovered a cure should communicate at once with the secretary, Mr. H. D. Tigwell, Greenford, Middlesex, who will be pleased to furnish full particulars. Will any members of the society whose Sweet Peas have been badly attacked by streak, and who are prepared to test remedies, please communicate with the secretary?

Double-Flowered Chinese Primulas.—The readiness with which fairly double forms of the Chinese Primula can be raised from seeds has led to the almost total disappearance of the very double-flowered kinds. The old double white, which used to be grown by the houseful to supply Covent Garden Market with flowers, is still occasionally to be met with, but the varieties with blossoms of an exceedingly duplex character which were raised by the late Mr. Gilbert when at Burghley seem to have totally disappeared. They created quite a *furor* in 1877 and 1878, when no fewer than five of them were given first-class certificates by the Royal Horticultural Society. The varieties were Earl of Beaconsfield, Marchioness of Exeter, Mrs. Barron, Princess, and White Lady. These could only be propagated by cuttings or layers, and consequently they realised good prices for some time.

Funeral of the late Martin John Sutton.—The funeral of the late Martin John Sutton took place at Sonning Church, near Reading, on the 17th inst. The edifice was filled with members of the family, relatives and friends, and a great many visitors were at the graveside. Simultaneously a memorial service was held at Greyfriars Church, Reading, where many members of Messrs. Sutton and Sons' staff attended. Among those present at Sonning Church were Sir Bowen Jones, Dr. Voelcker, Mr. Franklin Simmons, Mr. A. H. Matthews, the Mayor of Reading, M. Philippe de Vilhormin, Mr. N. N. Sherwood, Mr. John Collingridge, Mr. George Gordon and Mr. F. W. Harvey. At the memorial service at Reading the Deputy-Mayor and Corporation attended in their robes, others present being Lord Moreton and Mr. McRow of the Royal Agricultural Society, Mr. Powell of the Smithfield Club, and Mr. J. Lonsley of the British Dairy Farmers' Association. A great many wreaths and other floral tributes were sent, including one from the Agricultural Seed Trade of the United Kingdom.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Some Interesting Seedling Snowdrops.—Seedlings from *Galanthus cilicicus* (the so-called Autumn-flowering Snowdrop), from seed sown in 1909, are now blooming here profusely for the first time, but they did not commence to open until December. The pollen used was that of *Galanthus Elwesii*, but so far they do not seem to vary from the seed parent in any visible respect, the flowers, and especially the distinct foliage, taking after *G. cilicicus*. A good many of the flowers have a small green blotch on the outer petals, and they vary somewhat in height.—F. HERBERT CHAPMAN, Rye.

Snow in the Garden.—The summer aspect and conditions of the garden would in time become decidedly monotonous if such continued indefinitely, and the winter brings a welcome change and rest. The view presented on a winter morning is very impressive, the branches being weighed down, bowing, as it were, with reverence for Nature's fiercest element—King Winter. The old-fashioned winter may be considered by some to be a thing of the past, but a fall of snow, when it comes, puts quite a new series of pictures before lovers of Nature. Snow scenes in the garden are very beautiful, and though they may not last long in this changeable climate, they provide pictures not only for the memory, but for the camera, by means of which they can be recorded. The photograph I am sending will give some idea of the charm of conifers when partially clothed with a mantle of white.—E. E. CARTER, Romford.

Hints to Compilers of Schedules.—Promoters of horticultural exhibitions will now be arranging their schedules. I have often thought how much better it would be if, instead of cups and medals, useful articles were offered for prizes. From my own experience of those responsible for the necessary polishing, &c., they become a useless annoyance, and are often put away out of sight. As for medals, they are neither use nor ornament. For instance: A provincial exhibitor takes a collection to London at, often, great cost, and possibly obtains a bronze medal, which seldom afterwards will see the light of day. In place of such useless articles, why not a silver table-centre, Rose-bowl, corner table, silver flower-vases, a tall vase for specimen blooms, sugar-basin and cream-jug, tea and coffee service, and salver, with inscriptions? Such articles would be a pleasure for those responsible in the household instead of being a nuisance. I have heard ladies remark that flower show and other exhibition committees should have the assistance of ladies in the selection of useful prizes; then the household and posterity would look upon deserved honours with pleasure instead of the reverse.—A. C.

Gas Boilers for Greenhouse Heating.—Reading the article on these in THE GARDEN for November 29, page 600, reminded me of a garden in this locality, which I was looking round in the summer, where two small houses are so heated. The gardener, who went but three or four days weekly to this particular place, told me the gas-heating arrangement answered splendidly, and was easily managed by his employer on the days he was not there and in the evenings. I did not ask the name of the boiler used, but it was connected with the meter in the house and turned on and off from outside the greenhouses, around which were pipes of 3 inches diameter. In another large garden in this district the conservatory used to be warmed with a gas boiler, but that has since

rosea, and the smaller what I have hitherto called *N. sarniensis*. Both of them, like the cultivated bulbs usually sold, were very shy in flowering as compared with their hybrids, and also as compared with *N. Fothergilli* and *N. Meadowbanki*, which are the best of the old varieties for general cultivation. All of these flower early in comparison with the majority of the strain which I have been raising for years, and which are also much more floriferous than the imported bulbs. It is much to be desired that some resident in South Africa who knows the plants in their native country would give us particulars of the extent of variation which exists in Nature, and tell us something about their habitat and life-history. From their behaviour in cultivation I expect that most of them grow in places where the rainfall is very irregular and where frost does not occur.—H. J. ELWES, Colesborne.

Mildew on Roses in Canada.—

In your issue of November 8 your correspondent "E. M." writes of a preparation called Serum that he has tried with wonderful results as a cure for mildew on Roses. I should be very glad to hear whether other readers of your most useful publication have given Serum a trial, and with what results. Mildew is very troublesome here—Victoria, B.C.—and as my garden is near the sea and exposed to our prevalent cold winds, I have no doubt this aggravates the disease. I have tried spraying regularly with potassium sulphide, as recommended by the National Rose Society, also with formaldehyde, lysol, lime and sulphur, and some other recipes, all with little or no results. It seems curious that Roses that are very liable to mildew in England, in many cases are not so liable to it here, and *vice versa*; for instance, most Roses of the "mult-scans" type, like *Crimson Rambler*, do not suffer from mildew to the same extent as do the *wichurajanas*. All my *wichurajanas* were completely spoiled by mildew last summer, while *Crimson Rambler*, *Yellow Rambler*, *Ards Pillar*, *Flower of Fairfield* and *Mme. Alfred Carrière* were only slightly affected. Out of 123 different varieties of Roses of all types in my garden, only eleven showed no sign of mildew, viz., *Blush Rambler* (Cant), *Aglaia*,

A WINTER SCENE WHERE GARDEN AND WOODLAND MEET.

Conrad F. Meyer, *Jessie*, *Rayon d'Or*, the *Irish singles Elegance*, *Beauty*, *Modesty*, *Harmony*, and, lastly, the *Sweet Briars Lady Penzance* and *Meg Merrilies*. I should also like to know whether Serum is any good as a preventive or cure for black spot, which plague was introduced into my garden last summer by planting some "treasures"—*Juliet*, *George Dickson*, *Mme. Charles Lutaud*, *British Queen* and *Sunburst*. These were imported from France, and I apparently imported a fine crop of black spot into the bargain, much to my disgust, as I had had no sign of that trouble before. I treated the plants with formaldehyde, with no apparent result.—CHAS. R. SRRJEANTSON, Room 617, Sayward Building, Victoria, B.C.

been discarded for the usual method—firing. From an economical standpoint coke and coal are first; but for cleanliness, easiness and promptness—especially when dealing with small structures—gas wins.—C. T., Highgate.

Which is the Guernsey Lily?—I have read Mr. Jacob's letter on page 619, issue December 13, with interest, and after referring to the *Botanical Magazine*, plate 294, agree with him that this illustration represents the form which we now know as *rosea*, and not the form usually sold as *sarniensis*, which is inferior in size and much more orange in colour. Some years ago Lord Northbrook gave me some bulbs received from South Africa, of which the larger produced N

Early Tomatoes in Canada.—It would be interesting to know if any reader of THE GARDEN has grown the early varieties of American Tomatoes in England in the open. These, while rather coarse and small, are very hardy and early, and are grown in large quantities in Eastern Canada for early use. There are several varieties. Earliana is the first to ripen, and Chalk's Early Jewel comes about two weeks after. The seed is often sown outside early in May and the seedlings transplanted in the fields. Some years ago, near Montreal, I tried several of the early English varieties, and although they produced large fruit of better shape, they were not so early as the American varieties. In British Columbia, where the climate is about the same as in England, Earliana ripens in the open and produces good crops. I should be pleased to send seed to anyone who would like to try them this season.—T. SHEWARD, *Hillbank, Vancouver Island, British Columbia, Canada.*

Acantholimon venustum.—To the majority there is more than a modicum of truth in Mr. Malby's statement on page 622 that this precious midsummer-flowering alpine is difficult to propagate, though this may be done in a variety of ways. Further, your correspondent adds that "it is said to come well from cuttings when the necessary skill has been attained." And this is true. As Mr. Malby does not apparently furnish the "necessary skill," may I be permitted to supplement his remarks? In the first place, for all practical purposes, it is almost impossible to increase this species by division, its root system being generally opposed to it, and the plants of our acquaintance insufficiently large to admit of it being successfully done. Layering might be similarly dismissed; hence the cultivator is left with three methods of propagation at his disposal—cuttings, root-cuttings and seeds—all of which are good. Only one type of cutting, however, is of the least service, viz., that with a heel attached and one of comparative youthfulness. Cuttings such as this inserted in June or July give little trouble if the recently-formed shoots are secured. Almost pure sand is the best medium; a cold frame the best place. The root-cutting system is a far more reliable way to the alpine-grower of limited experience, though I do not know why Mr. Malby employed roots "10 inches long." In that length there would be ten cuttings if the root was of any size. Root-cuttings may be inserted in January and February, and are best in a greenhouse temperature or very gentle bottom-heat. The great obstacle in the way of root propagation is that of plants large enough to supply them, while there is a certain amount of risk to the plant in being disturbed and mutilated at the time named. Seeds, when procurable, present no difficulty whatever; the difficulty is in getting supplies, or at least any quantity, unless pollination is resorted to. This is, however, well worth while, seeing the value of the subject. Curiously enough, the commoner *A. glumaceum* will not only submit readily to division, but will root more freely from cuttings. Nodal cuttings I have found, however, are not of the least use.—E. H. JENKINS.

January 19.—National Chrysanthemum Society's Executive Committee Meeting.

THE FLOWER GARDEN.

THE HERBACEOUS SPIRÆAS.

WHILE the genus *Spiræa* is of considerable extent, the herbaceous species constitute but a comparatively small proportion of it. Those that do, however, possess an importance of their own, chiefly because of high decorative value for the most part, and particularly so when intelligently employed in water-side gardening. It is here, indeed, as also in the cool and rich soils of the garden, that the plants grow most luxuriantly, yielding of the abundance of their fleecy panicles in no ungenerous or uncertain way, and, provided space is permitted them, of that fine form which is among their greater assets. Hence to plant them well the gardener should know them well, know something at least of the development of a ten year old specimen in order that it may develop unhindered, unchecked by other plants whose habit of growth and stature may be of a like character. In such circumstances the noblest of these Meadow-sweets will embellish their surroundings, adding dignity and not a little importance to the spot they are intended to ornament. Too frequently, I think, the ultimate development of a plant is either unknown or insufficiently considered by the gardener, the net result a cramped or huddled mass incapable of displaying the plant at its best. One has frequently seen the Japanese Anemone, a plant endowed with rare beauty and fine form, so treated, crowded in by other subjects in such a way that one-half of the value of the picture is lost. So unique a subject is well worth considering apart, employing it rather in isolated groups or affording it a flanking position where it could be seen to advantage. When employed as a border plant, however, the great spread of its well-cut leaves is worthy of thought, and, given this, the right place or environment will follow in due course. These remarks are equally true of the bolder *Spiræas*, which can hardly be given a fair chance in an ordinary herbaceous border. By water-side or streamlet, or the approaches to woodland scenes, where the soil is cool and deep, the plants may be made much of, and in all such they may be grouped with a free hand.

Culturally, the chief item meriting attention is that once well planted they should remain for several years undisturbed; hence a deep bed of well-enriched soil should be at their command. Such a bed may be prepared in all cases, where possible, to a depth of 3 feet, to the lasting benefit of the plants. Those having more or less woody rootstocks, as in the case of the Goat's-beard *Spiræa* (*S. Aruncus*), appear to resent root disturbance and division to a much greater extent than such as *S. venusta* or *S. camtschatica*. The first-named species is somewhat slow in establishing itself, and, if divided at the same time, the belittling effects of the dual operation will be seen for at least three years, even with the most generous treatment. Where division of the roots is contemplated, early autumn will be found a good time—probably the best—though the work may be done at other times during the dormant period of the plants. The dwarfier border sorts, e.g., *Filipendula* and *palmata*, may also be divided in spring, with good results. Apart from these things, the plants are of the easiest culture, and are also perfectly hardy. Those named here are the most important

Spiræa Aruncus (Goat's-beard *Spiræa*).—In its fullest vigour this fine plant may reach to 5 feet high and fully as much through; hence it needs catering for on generous lines. It is a plant of the highest ornament, beautiful in the disposition of its tripinnate leaves, and most effective in the gracefully-drooping plumes of its creamy white flowers, which appear in summer-time. Well-marked varieties are *Kneiffi*, with very finely-cut leaves, and *plumosa*, whose foam-like inflorescences render it both valuable and distinct. The typical species, which has been known to cultivators for nearly three centuries, had a wide distribution in Europe, Asia and America. A lover of rich soils and moisture.

S. astilboides.—A species of unusual merit and excellence, one, indeed, that, like the Goat's-beard *Spiræa*, might be considered first-class for water-side planting. In the branched feathery panicles of its flowers it is quite distinct, somewhat dwarfier and perhaps even more graceful than the last named. The flowers are creamy white. Japan. A form known as *floribunda* is of more compact growth, and much in demand for pot culture.

S. camtschatica.—A giant in its way, attaining, on occasion, 8 feet or 10 feet in height. Though of a lesser leaf spread than either of the above named, the plant is in some respects one of the most remarkable, its huge palmate leaves and spreading, fleecy inflorescences crowning the tall stems rendering it quite conspicuous. As *S. gigantea* this fine plant has gained some notoriety, *S. rosea elegans* is perhaps one of the most showy of its varieties, but there are others intermediate in colour between this and the original. All are of the same habit and highly ornamental.

S. digitata.—A native of Eastern Siberia, usually in moist meadows and sub-alpine regions. The plant has a prostrate tuft of pinnate leaves, from which the flower-stems issue to a height of 4 feet or so. The flowers are white or pink tinted. *S. d. nana* is virtually an alpine of 6 inches or 9 inches high. It is a pretty and quite rare form, with pinky white flower clusters.

S. Filipendula (Dropwort).—This dwarf-growing British species is characterised by much dwarfness and by its deep green, interruptedly pinnate, glabrous leaves, forming a spreading, prostrate tuft close upon the ground. The type is not much grown, its double-flowered form, *S. F. flore pleno*, being much esteemed as a border plant. It is less than 2 feet in height. Flowers white, with pink buds in loose, spreading panicles. The species is quite distinct in its tuberous roots. Easily increased by division in spring. Quite at home in the ordinary border.

S. lobata (Queen of the Prairie).—One of the gems among border kinds, and a plant of the easiest culture in rich soils, in which it will attain fully 4 feet in height. The flowers are of rosy carmine colour, and are arranged in terminal panicles. With moisture the plant is of taller growth, and is welcome anywhere in the garden by reason of its colour. *S. l. magnifica* has deeper-coloured flowers. Most frequently found in catalogues as *S. venusta*. Native of North America. Easily increased by division.

S. palmata.—In every sense a first-class plant, at once indispensable to pot cultivation, to cool and moist border soils, or near the water-side, where it is capable of brilliant effects by reason of the richness and rarity of its broad, corymbose panicles of rosy crimson flowers. Distinct in

1.—MISTLETOE ON APPLE THREE YEARS AFTER SOWING THE SEED.

habit and with some refinement, it is a peer among its fellows. A plant of the highest value to the hardy plant gardener. It revels in moisture and rich soils, and, given these, in addition to their distant shade at midday, its flowers last a long time in perfection. I know of no herbaceous subject capable of affording such a mass of lovely colour as this, none more worthy the best endeavours of the gardener. All the varieties I have seen, judged from the standpoint of their picture-making effects in the garden, are secondary by comparison. They are *alba*, white; *elegans* and *maxima*, both having pink flowers. In response to a generous treatment, the plant may reach nearly four feet high, though the half of this is most usual. Native of Japan. Easily increased by division at any time when dormant.

S. Ulmaria.—This common British Meadow-sweet, the inhabitant of marshy places and wet ditches in many parts of the country, is rarely cultivated. In all its forms it is worthy of a place in the wild garden, if not quite good enough for the border now that the choice of subjects is so great. E. H. JENKINS.

SOME PECULIARITIES OF MISTLETOE.

As everyone knows, the Mistletoe is a parasite living upon various trees. It is most often seen growing upon the Apple, but it is also met with on the Hawthorn, Willow, Poplar, Lime, Maple, Mountain Ash, and even on Cedar of Lebanon and Larch. There is a popular impression that the Mistletoe has a great liking for the Oak, while, as a matter of fact, the two are seldom found together. The rare occurrence of Mistletoe growing upon Oak was held sacred by the Druids and regarded as a Divine gift. Dr. Bull, in a paper in the "Journal of Botany," only mentions seven authentic instances of the

growth of Mistletoe on the Oak in this country. Since then, however, other instances have been recorded.

The very slow growth made by the Mistletoe plant in the first few years of its existence has been a cause of anxiety to those who have fondly hoped to grow large bunches of Mistletoe in their gardens in a short space of time. Some idea of its rate of progress may be obtained from Fig. 1, showing what in reality is a promising young Mistletoe plant three years from the time of sowing the seed. The two large clusters of Mistletoe seen in Fig. 2 appear to be older than the Whitethorn which carries them. Such a result has been obtained by grafting the Mistletoe upon its youthful host. This is accomplished by removing the Mistletoe with a portion of the tree on which it is growing and grafting upon another tree.

Unquestionably, the most frequent host plant of the Mistletoe is the Apple, and it is notorious

2.—LARGE BUNCHES OF MISTLETOE GRAFTED ON WHITEHORN.

that some old orchards, notably in Herefordshire, carry heavier crops of Mistletoe than of Apples. A most singular thing concerning Mistletoe is that although it occurs on a wide range of trees and is so very common on the Apple, yet it is never found on the Pear. Some attempts to grow Mistletoe on Pear trees were made last year in Messrs. James Veitch and Sons' nursery at Langley by Mr. Allgrove, and the results were so remarkable that the subject has since been brought before the scientific committee of the Royal Horticultural Society. Mistletoe seed was sown on a number of Pear trees, and in many instances germination took place. In no case, however, did the Mistletoe get beyond the stage of germination, and no leaves were developed. The effect upon the Pear was very noticeable (see Fig. 3), for the Mistletoe, in its attempt to establish itself, killed all the tissue of the tree stem just within the bark, completely encircling the stem. All growth was killed above the point where the Mistletoe had germinated. C. Q.

THE KITCHEN GARDEN.

SEASONABLE NOTES ON VEGETABLES.

Winter Spinach.—In some soils Spinach at this season has a common knack of dying when the plants are a few inches high, owing, no doubt, mainly to the presence of some grub or insect pest attacking the roots. As a preventive sprinkle soot and wood-ashes freely over the plants and between the rows. During a spell of dry weather well stir the surface soil, about the plants especially; this will act as a deterrent to insect pests as well as a stimulant to growth.

Broccoli growing in heavy soil especially should have careful attention in the preservation of prematurely-formed heads by heeling them over to the north, thus giving double leafage protection to the forming heads. It is too early to heel over the main batch, those just now forming heads. From the side to which the plants are to lean dig out one spit of soil; then gradually heel over the plants by digging under the roots on the opposite side, thoroughly covering the stems with soil.

Mint.—This is one of the most important herb crops in the garden, and, all too often but meagrely produced, not succeeding as well as it should. The growth is usually too weakly to give the best results in the spring, when a quantity is required. Now is the time to endeavour to remedy such a defect and assist the next season's crop. If the roots have not occupied the same site more than three years, there is no need to replant the bed, although, where a quantity of green Mint is required, it is a good plan to make a small annual plantation in the spring. More suitable roots are then available for lifting for forcing early in the year. Cut off the current season's

3.—MISTLETOE FAILS TO GROW ON PEAR AND KILLS THE UPPER PART OF ITS HOST IN THE ATTEMPT.

growth close to the ground, clearing away all weeds, and lightly fork over the surface. If the soil is heavy in character, give a dressing of half-decayed leaves, vegetable refuse and wood-ashes. This, with the aid of frost and weather influence, will gradually work down among the roots and assist the next season's growth, inducing the production of stout, succulent stems and larger leaves. In the case of light soil, half-decayed manure as a mulch will render equal service.

Asparagus.—Remove the whole of the tops to within 2 inches of the soil and clear away all weeds. If the soil is heavy in character, lightly fork it over during dry weather and apply a compost, 2 inches thick, of half-decayed horse-manure, leaves, vegetable refuse and wood-ashes. Such a mixture is much superior to the all too free use of heavy green manure, which is a common plan, to be followed with a coating of soil dug from the alleys between the beds. The latter especially is neither desirable nor necessary, as such a thick covering of unsuitable material is liable to make the roots too wet and cold during the winter months, especially if the soil has not been deeply trenched or drained. In the case of light, well-drained soil, naturally or otherwise, a thicker coating of half-decayed manure can be used with advantage.

Potatoes.—Those stored in heaps in sheds, cellars or buildings need occasional attention, especially in removing diseased tubers. Neglect of this may mean serious loss, especially this season, when so many plots had the haulm affected by disease, but which had not developed it seriously in the tubers. In such a case the disease in the tubers is not so evident at lifting-time, but shows later on. Even if there are no diseased tubers, the turning over of the heap will assist the preservation of the tubers so much better than when allowed to ferment in a heap, which all too often happens when lifting is done during showery weather.

Manuring Ground.—During frosty weather, when the ground is hard, all manure that is required should be wheeled into position. It is a mistake to make deep ruts in soil when it is wet, as it takes nearly the whole of the summer to recover.

Spring Cabbages.—Whenever the soil is sufficiently dry, these will derive considerable benefit from hoeing or otherwise stirring the soil about them. This year slugs have been troublesome, eating large holes in the leaves and thereby weakening the plants. A dusting of soot, or soot and lime mixed, around each will act as a deterrent, and will provide the Cabbages with some food in a mild form.

Parsley.—In some soils, especially in the Northern Counties, a supply of fresh green Parsley is difficult to maintain throughout the winter. It is wise to make up a frame on a spent hot-bed, for example, filling it to within 6 inches of the

glass with a compost of light material, adding soot and wood-ashes freely. Lift plants from the spring sowing with a good ball of earth attached and transfer them to the frame 6 inches apart, thus giving abundance of air space. Keep the soil well stirred and remove the lights daily during fine weather, covering them with some protecting material during periods of frost. Frequently grubs attack the roots in some soils, causing the plants to die off suddenly. A thorough soaking with water to which is added petroleum at the rate of a wineglassful to three gallons of water will usually check the insect pests.

ERICA HYEMALIS, ONE OF THE MOST USEFUL OF THE WINTER FLOWERING GREENHOUSE HEATHS.

Cauliflowers.—Those not sufficiently advanced for cutting should be lifted and laid in cold frames or at the foot of a south wall, where they will continue to grow and mature their heads, which will be quite useful during the winter months.

Tomatoes.—Young plants should be kept quite close to the glass in a buoyant atmosphere to prevent their being drawn up weakly, or they will be of little service for the supply of winter and early spring fruit. White fly is at times troublesome. On the first sign of this pest carefully fumigate the plants.

E. MOLYNEUX.

Swanmore Park, Bishop's Waltham, Hants.

THE GREENHOUSE.

GREENHOUSE HEATHS IN WINTER.

A VERY important matter in connection with the successful culture of greenhouse Heath at this season of the year is to maintain a reasonable circulation of air, as, should the atmosphere become stagnant and over-charged with moisture, mildew is very apt to set in. Once it obtains a hold, it is likely to cause a good deal of trouble, though it may be combated

by dusting the plants with sulphur and increasing the supply of air. Properly attended to, however, this last will keep mildew entirely at bay.

Watering.—The watering of Heaths at all seasons is a very important matter, but in winter even greater care than usual is necessary. The soil in which Heaths are potted (peat and sand) dries very quickly once it has passed what may be termed the medium stage, but more particularly in the case of plants that are stood near the hot-water pipes. In any case, when a plant is watered, it should be thoroughly done, otherwise the soil may be moist at the top, and the bottom exceedingly dry. When this happens, the delicate, hair-like fibres are sure to suffer, and the plant quickly falls into ill-health. The above remarks apply, of course, with equal force to spring, summer or winter flowering varieties; but these last being at the present time most in the limelight, I will confine my remarks to them.

Of winter Heaths, *Erica hyemalis* has long occupied a prominent position, and to-day it is as popular as ever. It is largely grown in a few market establishments, and from these widely distributed, either by means of autumn sales or orders later on. The specimens of this Heath that are to be met with in the florists' shops of London are models of successful culture, and such a standard could only be reached by those who make a speciality of such plants, with houses specially adapted for their accommodation. They are practically all grown in pots 5 inches to 6 inches in diameter. A well-flowered specimen, such as is shown in the accompanying illustration, can be purchased at a very cheap rate.

The early history of *E. hyemalis* is obscure, but it is commonly regarded as of garden origin. At all events, it has been an exceedingly popular Heath for many years. The flowers in colour are rose and white. About thirty years ago a pure white form (*alba*) came prominently forward, and it is now largely grown. There is also a variety, *superba*, whose blossoms are of a richer colour than those of the type.

E. gracilis, now in flower, is, as a rule, at its best in the autumn and first half of winter. It is of a dense, twiggy growth, and bears its small rosy

purple blossoms in great profusion. There are some well-marked varieties of this, namely, *rosea*, in which the purple shade is to a great extent eliminated, the flowers being an almost clear rose tint; *nivalis*, under which name is included the best white, though in tone of colour there is a certain amount of variation; and *vernalis*, which does not bloom till the New Year, and is altogether of stiffer and more bunched growth than the others. *E. gracilis* readily lends itself to growing in those miniature pots which are now so much in vogue.

Another Heath whose blossoms are borne in the depth of winter is *E. melanthera*, which in its cultural requirements is one of the most accommodating of all Heaths. The flowers of this, which are borne in the greatest profusion, are mauve, with dark-coloured anthers. Though it can be flowered in 5-inch pots, larger examples are very

wilmoreana, rose and pink. The propagation of these Heaths and their culture during the earlier stages are very exacting, unless one has everything to hand for the purpose. Such being the case, it is, as a rule, most satisfactory to purchase a few examples just as the buds are developed.

After Flowering.—If, after the flowers are over, there is a desire to keep them for another season, the plants should be cut back hard. Then they will soon commence to push out new shoots, and as soon as these are about half an inch in length the plants may be repotted, using a pot a size larger than that in which they have been in before. Sandy peat forms the most suitable compost. It must be rammed down very firmly. Effective drainage, too, of course, is most essential. Kept in the greenhouse till growth is completed, these Heaths during the latter part of the summer may

THE GIBRALTAR CANDYTUFT (*IBERIS GIBALTARICA*) FLOWERING IN DECEMBER.

useful for decorative purposes. If potted on so as to obtain good-sized bushes, this Heath does not need to be cut back as hard after flowering as most of them do. A pleasing way of growing *E. melanthera* is to take the young plant in hand early and tie it to an upright stick. The leading shoot must be kept secured in position, when, with a little assistance in the way of pinching, the plant will assume the shape of a narrow pyramid, so different from its usual habit.

Other pretty winter-flowering Heaths are *E. cattra*, a dwarf, bushy-growing little plant with white flowers; and *E. colorata*, of upright growth, whose long-tubed, white flowers before expansion have a reddish tinge on the outside. Others that come in as succession to those above named, and the earliest of which may be had in bloom before winter has left us, are *candidissima*, white; *hybrida*, bright red; *persoluta* alba, white; *p. rubra*, reddish; *spenciana*, purplish lilac; and

be stood out of doors in order to ripen the wood and ensure the formation of flower-buds. H. P.

ROCK AND WATER GARDEN.

THE DESIGNING, CONSTRUCTION AND PLANTING OF ROCK GARDENS.

(Continued from page 634.)

Soils and Planting.—The question of soil can be dismissed very briefly, as it is rather a matter of the individual liking of the plant than a question of construction. For perhaps 50 per cent. or 60 per cent. of the plants used, fibrous loam, a little leaf-soil or peat (or both) and some good sharp sand are quite satisfactory. For the remainder it is merely a matter of varying the quantity of one or the other of the above constituents, and, in some cases, adding a proportion of limestone chippings. Any definite formula, except for particular subjects,

would be misleading. In the matter of planting, more can be said with advantage. An intimate knowledge of the plants used is the only sure guide. It is in the misplacing of various plants used that so many rock gardens fail. There are plants for sunny aspects, and those that prefer shade, some that revel in moisture, others that seem perfectly happy on the driest ledge. Nor is the appearance of the plant a safe guide to its habit. Take, for instance, *Ramondia pyrenaica*. To look at it anyone ignorant of its preferences would conclude that it would thrive almost anywhere, and for choice prefer an open sunny place with great depth of soil. As a matter of fact, some of the best plants I have seen were growing in vertical interstices between the cool north sides of some massive boulders.

So many books giving the experience of others are published now that there is not much excuse for many of the glaring errors that are made in this respect. The *grouping* of plants is a matter that cannot be learnt from books, however, but it is to this that many of the individual charms of the rock garden are due. Drifts and cascades of flower and foliage, in appearance tumbling from ledge to ledge, can be skilfully arranged, without such arrangements being obvious. A sunny slope planted with *Viola gracilis* in one large mass is very attractive, but if smaller and gradually diminishing plantings are made on the lower ledges to give the appearance of having seeded itself in all directions, the effect is much enhanced; and then, if the planting in its immediate vicinity is of a grey-leaved, yellow-flowered plant like an *Alyssum*, the combination becomes perfect. There are hundreds of studies that can be effected in this way without the introduction of one note of artificiality. Of course, to the man who revels in the microscopic detail of a plant because it is new or rare rather than beautiful, such schemes will not appeal. He will consider that a plant loses its individuality and its merit as an item in his collection if it shares the effect it produces with another plant. It is not for the collector I write, however. I have, indeed, little sympathy with the man who collects plants in the same spirit as the philatelist collects postage stamps. Colchester. GEORGE DILLISTONE.

THE GIBRALTAR CANDYTUFT.

(*IBERIS GIBALTARICA*.)

CONSTANT reference has been made in these pages to autumn-flowering plants for the rock garden, but in *Iberis gibraltarica* we have a subject worthy of special mention, since it flowers in the dead of winter. The plants overhanging rocks shown in the accompanying illustration commenced to flower in the early days of December. They were on December 18 in full bloom, and will continue to flower for some months to come. Each year this subject may be depended upon to flower at Christmas. There are two varieties, pink and white, and so freely are the heads of flowers borne that when seen from a distance the white form resembles little drifts of snow in the landscape. It is a suitable subject for a dry wall, providing it is given a fairly good rooting medium, when it will thrive in association with such subjects as Cotton Lavender, and *Cerastium tomentosum*. The sunny side of the rock garden suits it best, and it should be planted in a favoured niche, so that it may overhang the rockwork. It is both evergreen and hardy, and when once established will grow for years if not disturbed. Propagation is effected by cuttings, and it also produces seed.

TREES AND SHRUBS.

TREES AND SHRUBS WITH ORNAMENTAL BARK.

MUCH may be done, particularly when the pleasure grounds and shrubbery borders are fairly extensive, to make the whole place more attractive and interesting in winter by giving a little attention at planting-time to trees and shrubs of a deciduous nature which have brightly-coloured bark. There is additional justification for planting most of those named later in this article, as most, if not all, of them are attractive in summer, either on account of their graceful habit—the Silver Birch (*Betula alba*), for instance—or the highly-coloured foliage, a good instance of which we have in *Cornus alba* *Spæthii*.

A considerable list could be given of the numerous deciduous trees and shrubs with attractive trunks, branches or twigs. The intention here, however, is to limit the list to a comparatively few of the best which stand out prominently from the remainder and are particularly adapted for the purpose in view. These will be found valuable alike for both small and large gardens, for they may be planted as single specimens, small groups, or massed, where space permits, in prominent situations. The choice of suitable positions for planting the respective subjects has much to do with the ultimate success or failure of the project, more particularly in public parks and large private pleasure grounds. For instance, to show to the best advantage the undoubted beauty and attractive character of the White-stemmed Bramble (*Rubus biflorus*), it is desirable to have evergreens in the background, though not necessarily quite close to the Brambles. Again, masses of the Cardinal Willow are very nice in the shrubbery border, but they are far more attractive and thrive better by the water-side, even if it is only a ditch with water at some periods of the year, though, of course, if no water is available, this is impossible.

In numerous instances the best-coloured bark is that on the young shoots of the recent summer's growth. Such being the case, the aim of the cultivator should be, by pruning and other means, to induce the production of vigorous young growths. For instance, the *Salix* or Willows, when grown particularly for the winter beauty of the stems, should have the young shoots made the previous summer cut hard back in spring to within one or two eyes of the old wood, which in practice usually means down to near the ground. The treatment of the *Rubus* or Brambles is rather different. In this case the pruning is best done in autumn as soon as the leaves fall. It consists in cutting

out and carefully removing the old growths without damaging the young stems, the beautiful powder of bloom on which is easily disfigured.

The recognised methods of cultivation are suitable for deciduous trees and shrubs grown for their attractive bark in winter. In some instances, however, it is quite worth while supplementing the usual tillage operations with a little extra attention. Much thicker and longer growths, for instance, are made by the Brambles, Willows and *Cornus* when the ground is deeply dug and freely manured previous to planting and an occasional mulch of old, well-decayed manure applied. There

well known, the most noteworthy varieties being *Betula alba*, *B. Ermanni* and *B. ulmifolia*; *B. papyrifera*, with brown bark, and *B. nigra*, which has black peeling bark. *Fraxinus Excelsior aurea* receives its common name of the Golden-stemmed Ash from the colour of the bark.

It is interesting to note that three genera—*Cornus*, *Rubus* and *Salix*—are especially rich in shrubs with attractive stems in winter. In the *Cornus* or Dogwood family we have red, yellow and green twigged shrubs. *C. alba* and the varieties *Spæthii* and *sibirica* have red bark, *C. sanguinea* *viridissima* green bark, and *C. stolonifera flaviramea* yellow bark. The stems of some of the Bramble family are the most conspicuous among all shrubs, several of them looking as if the white-wash brush had been liberally used on the stems. This conspicuous character has led to *Rubus biflorus* being popularly termed the Whitewash Bramble. Almost or quite as good as this species—some growers say they surpass it—are the newer Chinese species *R. giraldianus*, *R. Veitchii*, *R. tibetanus*, *R. lasiostylus* and the variety *R. biflorus quinqueflorus*. The showiest of the Willows are *Salix alba* var. *cardinalis*—the Cardinal Willow, with red bark; the Golden-stemmed Willow, *S. alba* var. *vitellina*; and *S. daphnoides*, with a conspicuous bluish white bloom or powder on the stems. There are several other Willows with coloured stems which might be used if space permits. *Berberis virescens* has red stems, while *B. diotyophylla* is also attractive in winter. The green stems of some of the *Cytisuses*, *Spartium* and *Genistas* may also receive consideration. A. O.

SILVER BIRCHES IN THE WOODLAND, SHOWING THEIR WINTER BEAUTY WITH A BACKGROUND OF CONIFERS.

is another side to the question, and that is, with few exceptions, among the shrubs the best results are obtained with young plants, so that after a few years of hard pruning the Willows and Brambles should be grubbed out and replaced with young stock.

Among trees, the most noteworthy with conspicuously-coloured stems or trunks are *Acer pennsylvanicum* (syn. *striatum*) and the variety *erythrocladum*; the Chinese Maple, *Acer Davidii*; the *Birches*, the white bark of which is fairly

addicted to mildew. The colour I have left till the last, because it is very difficult to accurately describe. One turns to the National Rose Society's official catalogue—"coppery yellow." That would seem to point to a predominance of yellow. The raiser has, however, a different idea. He calls it "deep orange red, shaded bronze apricot red," pointing to a predominance of red. To attempt to describe the colours in two words is futile; it simply cannot be done. I think all the various colours named are there, but not in the order of

ROSE GARDEN.

IN A HAMPSHIRE GARDEN.

SOME OF THE NEWER DECORATIVE ROSES.

(Continued from page 632.)

Mrs. Frederick W. Vanderbilt (S. McGredy and Son, 1913).—My choice of all the Lyons-raised seedlings of this, or, for that matter, of any other raiser. The growth is further away from the type, and is vigorous, free and branching, and not stiff. The flower is very fragrant, and although the plant is not mildew-proof, it is not particularly or badly

their relative importance. For example, a yellowish copper is nearer the mark than a coppery yellow. In the same way, if the raiser had said a reddish orange, shaded bronze red apricot, I am inclined to think he would have been much nearer the actual colour. Taking out the dominant colours, we now get copper, orange and apricot. They are all there, and at respective stages each is the principal colour in the flower—copper in the bud, orange in the half-open flower, and apricot in the fully-expanded bloom, with all the half shades in between. I do not think there is any red in the flower except such as forms a constituent of the copper. The advent of Pernet-Ducher's strain has made a vast difference to the colour of our garden Roses; but it has, unfortunately, introduced several elements which are by no means to be desired. An inexplicable dying back of seemingly healthy wood, a bad habit of growth, and a marked hereditary tendency to black spot are on the other side of the picture. These will all have to be bred out before we can look for a good bedding Rose in this section, and the Rose under notice has progressed as far in that direction as any that I have come across.

Mrs. George Preston (Alex. Dickson and Sons, 1910).—One of the new Roses that by reason of its colour perhaps has been somewhat overlooked. I cannot account for it in any other way. I remember once hearing one of the oldest and most respected of our Rose nurserymen saying, "We don't want any more pink Roses. I won't look at a pink Rose." I cannot understand that point of view. To be logical, it must mean either that pink is a bad colour or that pink Roses have reached perfection and cannot therefore be improved upon. Now, neither of these propositions is true. Perhaps what was meant was that pink as a colour was out of fashion. Be all that as it may, I would welcome any Rose if it was better than a Rose already in commerce (which it resembled), be the colour what it might. To get back to Mrs. George Preston, this is a warm silvery pink. The flowers are of good size and substance, freely produced, sweetly scented and particularly good in autumn.

Mrs. Gordon Sloane (Alex. Dickson and Sons, 1912).—I think this is going to be a good decorative Rose. I have only one plant of it, and therefore one has to speak a little charitably. The colour is distinct and good, coppery pink and flesh, especially in the early flowers. It is a good grower, of that free-branching habit that is so essential to a free-flowering Rose; strongly perfumed.

Mrs. Joseph H. Welch (S. McGredy and Son, 1911).—Those who only know this Rose from the specimens seen in the exhibition boxes at shows can have but very little idea of it. The bud or half-open flower—it is very often nothing more than the former that is exhibited—is very fine, but a young flower "fully" open is much more

beautiful. As a matter of fact, it is almost a single, and a few young flowers in this stage are strikingly beautiful as cut blooms. It is not an ideal bedding Rose, owing to its habit of growth, which is tall and whippy; but it is a most interesting Rose to grow, and is sweetly scented.

(To be continued.)

NEW AND RARE PLANTS.

FIRST-CLASS CERTIFICATE.

Cattleya percivaliana alba Lady Holford.—An exquisitely beautiful flower of purest white,

and of a free, easily-expanding character. The flowers are moderately large and sweetly scented. These were exhibited by Messrs. W. Wells, Limited, Merstham.

Cypripedium nitens leeanum var. smaragdinum (C. leeanum giganteum × C. Sallierii hycanum).—Sepals, petals and lip uniform greenish yellow; dorsal sepal of greenish tint, obscurely mottled and heavily tipped with white. From F. T. Hanbury, Esq., East Grinstead.

Odontoglossum Cleopatra Rosefield Variety.—Sepals and petals rich cinnamon brown, faintly bordered yellow and tipped with white. Lip crimson, with yellow crest, reticulated and heavily tipped with white. From de Barri Crawshaw, Esq., Sevenoaks.

Odontioda Langowoyi (O. Uro-Skimmeri × Miltonia schröderiana).—Sepals and petals acutely pointed, crimson, green tipped. Lip ruby red, broadly tipped with white. From Messrs. Charlesworth and Co., Hayward's Heath.

Cypripedium bourtonense (C. nigrum Harefield Hall × C. Blanche Moore).—A flower of giant proportions. Sepals and petals greenish brown, with pouch of the same colour. Dorsal sepal 4 inches across, greenish, copiously blotched brown and heavily bordered with white. From G. F. Moore, Esq., Bourton-on-the-Water.

The foregoing were shown at the committee meeting of the Royal Horticultural Society on December 16.

THE TANGIERIAN IRIS. FLOWERS BLUE WITH A BRIGHT GOLDEN BLOTCH ON THE FALLS.

THE TANGIERIAN IRIS.

(IRIS TINGITANA)

This lovely Iris was introduced from Tangier as long ago as 1872. When successfully grown, it is looked upon as one of the most charming species of the genus. It shows a marked liking for a warm, sunny situation, which is not surprising when we consider its habitat. In favoured counties like Devon and Cornwall it does well, especially if given a sandy, gritty soil to which lime rubble has been added. During the winter it needs protection from heavy rains. Some exceptionally fine plants in full flower were shown

recently before the Royal Horticultural Society by Messrs. Barr and Sons. The plants created great interest and admiration by reason of their healthy growth and lovely flowers. These plants had been grown under glass from strong, selected bulbs, which were potted up in early August and given cold-frame treatment. It is worth noting that this Iris makes a fine pot plant for the greenhouse, and may be lightly forced like the Spanish Iris. The flowers vary in the upright standards from light to dark blue, the falls usually of a paler shade. Each has a bright golden blotch. Its time for outdoor flowering is May and June, but when grown as a greenhouse plant it may readily be had in bloom at this season.

AWARDS OF MERIT.

Chrysanthemum Bertha Lachaux.—A very useful and beautiful late-flowering decorative variety of deep pink colouring. The variety is of the decorative class, the florets spreading or slightly reflexing.

Carnation Philadelphia.—This is one of the cerise pink shades, somewhat deeper than Lawson,

GARDENING FOR BEGINNERS.

HINTS ON PLANTING NEW SHRUBBERIES.

WHETHER the proposed new shrubberies are to be large or small, every effort should be made to prepare the soil well, to put in the most suitable kinds of shrubs, and to arrange them in the most attractive way. Even a very small shrubbery makes a dwelling-house look

really rich soil helps matters wonderfully; but there is a great deal that is of poor quality, and those persons who have to grow shrubs in such should make it as suitable as possible before putting in the plants. Trenching is the first consideration. Whether the soil be rich, gravelly, sandy, peaty or clayey, it must be trenched to a depth of at least 20 inches. Thirty inches would be better, especially in cases where the larger kinds of shrubs are to be grown. In carrying out the work, the cultivator must keep the surface soil on the top, simply turning it over and breaking it up. The subsoil must be kept below and well loosened with the end of the garden fork. If there is a grass turf to deal with, the latter must be buried about nine inches below the surface and chopped into squares. In a short time it will commence to decay and supply nourishing food for the shrubs for a considerable time. In every case the best soil must be kept near the surface, but where poor soils obtain, the most nourishing foods should be placed on the surface and just below it, as, owing to the porosity of the soil, the rains will soon wash down all the best portion below the reach of the roots.

Planting the Shrubs.—In the case of a new shrubbery, it will be found necessary to fill up space with temporary shrubs, those intended to remain permanently being planted first. In Fig. A two forms of shrubberies are shown, one near a wall and garden path, and the other an irregularly-shaped one on a lawn. In the first named, herbaceous and other flower roots may be used to fill in space, so that all the shrubs put in will be permanent subjects. No. 1 shows a climber on the wall; No. 2, a standard deciduous tree; No. 3, a nice specimen conifer; No. 4, a dwarf shrub; and No. 5, the edging and portion of path. In the large

lawn bed, Nos. 6, 7 and 8 denote the larger permanent shrubs, all others being planted to fill up the vacant space. Some of them will remain in their positions for probably a dozen years before it will be found necessary to remove them to allow sufficient space for the others to grow in. Fig. B shows, at Nos. 1, 2, 2, the way to group shrubs on a lawn. There may be as many as seven or even twelve in a group, but in each case they should be so disposed that every specimen can be seen from whichever point it is viewed. After covering the roots

A.—PLANTING CLIMBERS AGAINST A WALL AND SPECIMEN TREES IN THE OPEN.

B.—SHOWING HOW TO GROUP SHRUBS FOR EFFECT.

more substantial, inviting and comfortable. Furthermore, shrubs afford the cultivator a great amount of interest. He derives pleasure from watching their growth, and in association with them he can, all the more effectively, arrange other subjects in the garden. Some shrubs look best when grown in beds on the lawn, others are more suitable for growing in side borders near paths and walls, while many are the most effective when treated as specimens.

How to Prepare the Soil.—Very fine shrubs can be grown in quite poor soil if it is well treated. So many cultivators are under the impression that it is useless for them to attempt to form a shrubbery because the rooting medium is indifferent as regards quality. Of course,

lawn bed, Nos. 6, 7 and 8 denote the larger permanent shrubs, all others being planted to fill up the vacant space. Some of them will remain in their positions for probably a dozen years before it will be found necessary to remove them to allow sufficient space for the others to grow in. Fig. B shows, at Nos. 1, 2, 2, the way to group shrubs on a lawn. There may be as many as seven or even twelve in a group, but in each case they should be so disposed that every specimen can be seen from whichever point it is viewed. After covering the roots

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Pleasure Grounds.

Paths.—Any paths that may have been cut up through the heavy traffic of alterations should, if possible, be put right at once. It may mean that the whole surface of the path will need breaking up and regravelling. In such a case the old gravel should be carefully levelled, and, if a fairly wide path, sufficient camber should be allowed to take the water away nicely, a flat path soon wearing into holes through the water standing on it. If the surface of the old gravel is left moderately rough and the fresh gravel is carefully levelled and well rolled, the whole will become thoroughly consolidated and not be likely to pick up.

The Flower Garden.

Double Arabis.—Considerable trouble is being experienced in these gardens through the birds pulling up or breaking off the young plants in the flower-beds. Whether this is pure mischief, or whether they do it to more easily get at the small black slugs that secrete themselves on the under part of the foliage, I do not know; but anyone experiencing the same trouble would be well advised to place black cotton over the beds some 8 inches or so inches above the plants.

Nicotiana Colossea variegata.—Cuttings of this beautiful subtropical bedding plant should be inserted in a brisk bottom-heat as they become fit. Side growths, I find, root much more quickly than the tops of old plants, and if rooted early in the year and potted on as they require it, they should make quite nice plants by planting-out-time.

Dracæna indivisa is a most useful subject in the flower garden, and young plants raised from seed during the past spring should make quite nice-sized plants for dotting purposes if kept nicely moving through the winter and spring. Potting on should be done at any time as they require it, 6-inch pots being about the right size for plants raised this year, and should carry them till they are required for planting out.

Acacia lophantha and **Eucalyptus** raised during the summer should also be repotted as they become fit, as if good, well-turished plants are required, the pots must not be allowed to get too full of roots before the plants are potted on. Very little heat is required for these subjects; but if the plants are small, it might be wise to keep them nicely on the move during the winter.

Plants Under Glass.

Pot Roses.—Plants required for fairly early blooming should be removed under cover at once, where they should be allowed to get fairly dry before the work of pruning is commenced. Unfortunately, all Roses have continued growing, or at least held most of their foliage till now. What effect it will have on their flowering remains to be seen, but they will not get much rest this season. Plants permanently planted in the houses, whether for covering the roof or in beds, may be pruned at once. They should then be given a thorough cleansing, also the house, after which a little of the surface soil should be removed, substituting this with a little fresh soil to which has been added some half-spent manure and bone-meal. The borders should also be thoroughly well watered, the subsequent treatment accorded the plants varying with the date they are wanted in bloom or with the varieties.

Pruning.—The Teas and Hybrid Teas do not require such severe pruning as the Hybrid Perpetuals, though it is doubtful if there are many of these latter grown now in private places, except perhaps Frau Karl Druschki, Mrs. J. Laing, Captain Hayward and one or two others.

Imantophyllum.—This most useful plant may be had in flower over quite a long season if part of the stock is introduced into heat and the remainder allowed to come along gently in quite a cool house. Plenty of manure-water is necessary when the plants are throwing up their flower-spikes, and this makes quite a lot of difference not only to the size and colour of the flower, but to the foliage as well.

Amaryllis.—Many of the early-flowered bulbs last year are now pushing their flower-spikes, and directly this is noticed they must be placed

in a light position in one of the houses. Should they be wanted quickly, they will stand a fair amount of heat; but care must be taken with the watering, or the foliage is apt to overgrow the flower-spikes.

The Vegetable Garden.

Ridging the Soil. in addition to trenching, is a decided advantage where the soil is of a heavy clayey nature. Such treatment allows as much of the soil as possible to become thoroughly disintegrated with the action of frost and air, so that when the season of sowing arrives it is drier and breaks down nice and fine, and so provides a good seed-bed. This latter is one of the essentials towards the successful cultivation of all classes of vegetables, and in soils of varying character different means must be employed to attain the desired end.

Fruits Under Glass.

Tomatoes.—These call for careful treatment at this season, and where the plants are ripening their fruit, too much moisture must not be afforded at the root, nor must the atmosphere of the house contain too much moisture, or heavy foliage and little fruit will be the result. If the trusses are fairly well set, the points of the shoots may be pinched out and thus induce the fruit to swell quickly.

Fruit-Houses generally that have been started some little time must be kept steadily moving, making no attempt to hurry them until the days begin to lengthen some little time hence, at the same time maintaining the proper amount of heat and humidity in the houses to ensure the growth coming away strongly.

Strawberries.—Good batches of these may now be placed indoors. The first batch will probably have been in a week or two, and if in one of the fruit-houses that have been started, the gentle rising of the temperature should suit them well. If the successional batches are put in as other houses are shut up, they will naturally produce a nice succession of fruit. Sufficient water should be given at this season to keep them from getting really dry, increasing it accordingly as the plants make growth.

Hardy Fruits.

Raspberry Belle de Fontenay.—This autumn-fruiting Raspberry has this season been more prolific than ever I have known it, and though the flavour is not so good as at midsummer, it is, nevertheless, very useful during September, October and November, and even in December we have gathered one or two good dishes of fruit. It is an excellent grower, and where Raspberries are in much demand, a row or two of this variety is well worth growing.

THOMAS STEVENSON.

(Head-gardener to E. Mocatta, Esq.)

Woburn Place Gardens, Addlestone, Surrey.

FOR NORTHERN GARDENS.

The Flower Garden.

Digging and Trenching.—This work should be pushed forward in open weather, but be left severely alone during frost.

Calceolarias.—While these and other half-hardy plants in frames should be well exposed in open, mild weather, they must be sufficiently protected from frost. Should severe frost set in, it will be advisable to supplement the mats with a covering of straw, and some loose litter should also be placed round the box of the frame.

Protecting Early Bulbs.—Where Snowdrops and Scillas are grown in square or oblong beds for cutting purposes, a one or two light frame may in turn be placed over Snowdrops, Scillas or Chionodoxas, Dog's-tooth Violets and Daffodils, thereby hastening the flowering period by a fortnight or more.

The Rose Garden.

Late Operations.—Where any rearrangement of beds or their occupants has been contemplated and the work cannot be got through for some little time, it will be wise to lift the plants without delay and lay them in by the heels in a vacant piece of ground, carefully named, deferring the planting of them in their permanent places till February

Rose Hebe's Lip.—This is one of the most beautiful varieties of old garden Roses, and not very well known, I think. It is a white Rose with a tinge of bright pink on the tips of the petals, which much enhances its beauty, especially in the half-opened buds. I purchased it from Messrs. Dobbie and Co. before they left Rothesay.

The Pleasure Grounds.

Trees and Snow.—When a heavy snowfall occurs, valuable ornamental trees are frequently damaged through the weight of accumulated snow breaking the branches. If a heavy fall of snow occurs, therefore, a rake or long pole should be employed to dislodge the snow from spreading ornamental trees such as Piceas, Pinuses and Cedars.

Plants Under Glass.

Callicarpa purpurea.—This attractive purple-berried stove shrub is now almost over for the season, and may be cut down to within about six inches of the ground, either to be grown on again or to furnish cuttings for young stock.

The Newer Winter Begonias.—Begonia Gloire de Lorraine is as yet indispensable, but some of the newer and larger-flowered varieties should also be grown by those who have accommodation. Such varieties as Miss Clibran, Optima, Progress and Bank Hall Beauty can be recommended without hesitation. I would also put in a plea for old B. manicata.

Cinerarias.—These have made much growth on account of the mild autumn. Vaporise occasionally for green fly, and on the first appearance of the leaf miner, spray with Quassia Chips Extract.

Forcing Camellias.—These old-fashioned plants should not be subjected to hard forcing; but if a few plants are introduced to an intermediate temperature now, they will prove very useful for the conservatory by the beginning of February. Never allow them to suffer for the want of water, or bud-dropping will be the result.

Bulbs.—With the lengthening days these will respond more readily to a little forcing, and they should be brought forward in considerable batches, as it is in the early part of the year that they are most prized. Daffodils will not stand such hard forcing as Hyacinths and Tulips.

Fruits Under Glass.

Cordon Trees.—For Apples or Pears, the cordon system has much to recommend it, its two chief advantages being that one is able to obtain fruit at the earliest possible moment, while by it one can secure the maximum amount of fruit in a given space.

Potting.—No time should be lost in procuring the trees, and if they are to be potted, the operation should be performed as soon as the trees come to hand. Generally speaking, pots 12 inches in diameter will be sufficient at first. Drain the pots carefully and use a compost of about five parts of sound, fibrous loam to one part of rotten cow-manure. Ram firmly with the potting-stick and leave quite 2 inches for water. Water through a rose and plunge the plants outside among some light material, standing the pots on a slate to prevent the ingress of worms.

The Vegetable Garden.

Jerusalem Artichokes.—This crop requiring a long period of growth, it cannot be planted too early in the year, provided that the ground is in good condition. Keeping this in view, the quarter, if not already trenched, should be done so at once if the weather permits. A rather light soil suits this crop best, and it should not be too highly enriched, or stems instead of tubers will be the result.

Home-Made Pea Guards.—An effective Pea guard can be made by tacking 18-inch wire-netting (half-inch mesh) on to lengths of wood 2 inches square. A man at each end then lifts the guard on to the line of Peas, and draws the lengths of wood slightly closer till an arch is formed over the line of Peas.

Pea Stakes.—No time should be lost in preparing a sufficient quantity of these. Beech, Elm and Hazel all make first-rate Pea stakes. Those who cannot get natural ones must fall back on wire-netting or wire hurdles.

CHARLES COMFORT.

Broomfield Gardens, Davidson's Mans, Midlothian.

GARDENING ACROSTICS.

AS announced in our issue for November 22, we are publishing eight gardening acrostics, to be divided into two sets of four each. Each light correctly guessed will count one, and also each "first" and each "last." Thus, supposing the whole is China (firsts), Aster (lasts), the full marks will be seven—one for China, one for Aster, and one for each of the five lights C . . . A, H . . . S, I . . . T, N . . . E and A . . . R. Hence, suppose a competitor got everything right but the light I . . . T, he would count six, and it would not matter if he attempted to solve that particular light or not.

Those entering for the acrostics must observe the rules published on page 607 of the issue of December 6.

DOUBLE ACROSTIC No. 4.

A very big book, written in a very big way almost exactly 200 years ago. The last of its type.

Firsts—the type.

Lasts—the author's surname.

1. I once gave the Dutch a horrid fright.
2. A famous book, written for Old England's glory.
3. A great Russian botanist of modern times.
4. A gardener once saw the capability of the spot and made a lake and his fortune. Where was this at?
5. The Strawberry Tree.
6. The surname of the man who gave us "the most complete book of Gardening ever published." A regular gardening octopus in its wide embrace.

Solutions of the above must be sent so as to reach the Editor at 20, Tavistock Street, Covent Garden, London, W.C., not later than the first post on Saturday, January 3, 1914. Mark the envelope "Acrostic" in the top left-hand corner.

SOLUTION AND NOTES OF ACROSTIC No. 2.

NECTARINE—RASPBERRY.

*	1.	N	UPHA	R
†	2.	E	RIC	A
‡	3.	C	ARELES	S
§	4.	T	ULI	P
	5.	A	RA	B
¶	6.	R	IC	E
**	7.	I	NFERIO	R
††	8.	N	ECTA	R
‡‡	9.	E	BON	Y

Firsts—If a Peach stone be sown, it is quite uncertain whether the resulting plant will be a Peach (downy) or a Nectarine (smooth), and *vice versa*. *Lasts*—Botanically, a Raspberry is such a fruit. The Red Antwerp and the Yellow Antwerp were known considerably more than a hundred years ago. * Nuphar is thus described in "Nicholson's Dictionary of Gardening": "The yellow Water Lily of our streams and pools is a Nuphar." † Ericas come from South Africa. They were a very popular genus for greenhouse cultivation about the sixties and seventies. ‡ Gooseberries are called "berries" among Gooseberry show people. Careless, raised near Birmingham, is an old variety of excellent flavour. In the "Gooseberry Grower's Register" for 1889 it occupied the premier position as the heaviest white berry. § The Tulip is thus described in

"Le Floriste Franois" in 1654, page 206. This is an exceedingly rare book on Tulips. It is the first floral monograph ever published. || An interesting account of the Arab influence on the coasts of the Mediterranean is to be found in "Wanderings of Plants and Animals," by Heyn and Stallybrass, pages 37 and 38 and 336 and 337. * Rio was the staple food of the poor Indian for generations before it was introduced to America.—"Wanderings of Plants and Animals," page 383. ** See any book on botany for description of terms. †† In *Fritillaria imperialis* (Crown Imperial) the nectaries are in shallow excavations on the inner side of the perianth leaves near their base. Each one exudes a large drop of nectar, which is seen on looking down into the flower. ‡‡ *Diospyros ebenum* makes the best Ebony. See such a book as "McCulloch's Commercial Dictionary," under "Ebony."

*** Owing to the Christmas holiday, this issue had to go to press before the last day for sending in solutions of Acrostic No. 2. The results of this will therefore appear in our issue for January 3, 1914, together with the results of No. 3.*

THE NAMING OF TULIP BREAKS.

MAY I thank Messrs. Leak, Krelage and Needham for their most interesting letters? The naming of breaks has become an important question to both the sellers and the purchasers of Tulips. The striped flowers that we used to root up and consign to the rubbish heap are going to be marked, saved and "grown on." Already I hear of one of the largest wholesale firms of Holland casting about to secure stocks so as to be in a position to serve their American customers. It is a straw which shows the direction of the wind. Only let the fashion grow, so that these broken Tulips command a ready sale, and we shall all of us be saving all we can. This is when the difficulty will begin. Clara Butt may break in any or all of the many gardens in which it is grown. As the custom is at present, there is nothing to prevent Mr. Leak giving the break one name, Mr. Krelage another, myself a third, and so on *ad infinitum*. When only an odd Cottage or Darwin break was picked out here and there, it did not very much matter how the names were given; but let the numbers appreciably increase and these broken varieties become fashionable, then some hard-and-fast system becomes imperative, or their nomenclature will soon be in a hopeless state of confusion.

Mr. Needham, in THE GARDEN of December 6, has told us how the Tulip men of the past and present avoid this. The underlying principle of their nomenclature is "Once a Sir Joseph Paxton, always a Sir Joseph Paxton." The rectification or the becoming striped is only a stage in a bulb's life-history, and the change does not make a new variety any more than the growth of whiskers, beard and moustache on the smooth face of John Smith makes the aforesaid John Smith into Peter Jones. They speak of a self-coloured Sir Joseph Paxton as Sir Joseph Paxton breeder, and when it is striped, as Sir Joseph Paxton rectified, or, more usually, they give the type of rectification into which it has broken—if with only a light marking on the edge of the petals, as feathered, or if with much colour all over them, as flamed and feathered. Every break must take on, roughly speaking, one

of the other of these markings. So a Cottage or a Darwin variety will always give a lighter or a darker break corresponding, I believe, to the "feathered" and the "flamed and feathered" of the strict florists. From a conversation I have had with Mr. Leak, I gather that this is his experience. It certainly is mine, only I find that there is an almost inevitable tendency for the delightful light breaks to become dark in the course of a year or two. How well I remember an exceedingly lovely broken Tara being shown at one of the last of the Temple Shows by Mr. B. S. Faudel-Phillips, who kindly gave me half-a-dozen that same autumn. What has happened? Mine became so heavily coloured that they lost all their beauty, so much so that last year I consigned them all to the "mixed." At the Perpetual Flowering Carnation Show in December I met Mr. Faudel-Phillips' gardener, and he told me that theirs have gone just like mine. I mention this because I believe that there is a tendency for all breaks to go much the same in the course of time. As Mr. Needham has told us, the various strains of Sir Joseph Paxton are now practically all one. Whatever difference there once was has not been retained.

Naming difficulties, of one sort or another, have always been a Tulip appendage. Nothing can well be simpler or better than the practice of the strict florists, and if their flowers were the only ones, and they themselves the only cultivators, there would be an end of the matter. To-day, however, instead of being the only growers of Tulips, they are but a very small minority, and it is a case of other men, other manners, both with respect to the types that are esteemed and the system of naming. Again, we must remember that what I may call the simple and expressive system is, after all, but a comparatively modern invention, and that we never read of Semper Augustus, or Gonda, or Admiral van der Eyck of the Tulip mania time, or of Zomerschoon or French Crown, which are older by far than Sir Joseph Paxton or Trip to Stockport, as being flamed or feathered. (It could not be done now if one wished, for no one knows from what they spring.)

Here then, is our difficulty and perplexity. We have two types of flowers, two types of growers and two methods of naming; one scientific and expressive, one "anyhow." Should we continue as we are, or should we try to establish the newer and more accurate system? I should like to do so if I thought it practicable, but I do not. It might make confusion doubly confounded. I do not know if I have found the Philosopher's Stone, but I have been busy looking for it ever since I read Mr. Krelage's article, and here is the result of my efforts. I would propose that the joint committee who will meet at Wisley draw up a list of break names for all the Cottage and Darwin Tulips that they know of, and that then they should strongly recommend everyone to adopt them. Thus, supposing the name *Austraha* is given to the rectified form of Clara Butt, everyone would know what to call his break, for all breaks are the same, whether they take place at Haarlem or Wisbech or Whitwell. Some might be darker and some lighter at the start, but the difference will not continue for long; but while it lasts it could easily be noted in the catalogue description. This scheme would leave all existing names as they are, it would be carrying out the principles of the newer nomenclature of the show men, and it would provide a series of ready-made pigeon-holes, into which we could all put our breaks. If a new variety is

introduced, the introducer would give it a double name, one for its breeder, the other for its rectified state.

If this suggestion is thought feasible and ultimately adopted, although it will not altogether appeal to my reason it will to my sentiment, for the contemporaries of Wearmouth and Gaerœd (1937) spoke of Gonda and Semper Augustus simply, so in sunning we shall but be one with them, even if they did it through ignorance and we because of expediency. JOSEPH JACOB.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

BELLADONNA LILIES NOT FLOWERING (L. M. F. F.).

The reason why your plants of *Amaryllis Belladonna* do not flower is possibly the bulbs are not ripened properly in the position where they are growing. As a rule, the best results are obtained when the bulbs are growing at the foot of a warm wall; in such a position they are usually sure of well-drained ground, while the heat from the wall assists in ripening the bulbs. Perhaps your plants would give more satisfactory results if you moved them to a position at the foot of a greenhouse wall.

ANTIRRHINUM DISEASE (E. B.).—The Antirrhinum which you now send, and which have arrived in excellent condition for examination, packed in moss in a tin box—we wish all our correspondents would adopt this fashion of packing, or improve upon it by folding the specimens in a piece of soft paper (not cotton-wool) first—enable us to say that they are attacked by a fungus. This fungus, which is apparently a species of *Septoria*, is fruiting abundantly, and by means of the spores which it produces will, no doubt, travel very quickly. Not only are the leaves attacked and brown spots produced upon them, but there are patches on the stems which also show the trouble, and which soon spread through the stem, killing it at this spot and, of course, all above the spot attacked. It would be well to remove all the plants affected as completely as possible and burn them, taking care that the spores are destroyed as little as possible in the doing of it. Immediately after this, spray the plants with a solution of potassium sulphide at the rate of 1oz. to three gallons of water.

ROSE GARDEN.

ROSES INJURED BY INSECTS (F. G. P.).—We rather think the trouble arises from earwigs, which have been very prevalent this year. We also think the browning of the flowers has been rather the result of the washes applied. We think if you used a strong solution of Quassia chips you would at least make the foliage objectionable to the insects. Also give the soil a good dusting of soot.

TREATMENT OF AMERICAN PILLAR (A. E. S.).—In the case of fine, vigorous growers like American Pillar, the young growths should always have separate supports, such as bamboo canes, allotted to them, so that they do not impede the development of the flower-clusters or hinder their own growth from maturing. Where possible, the old growths should be almost isolated, so that each may display the fine trusses to the best advantage. This also ensures the more rapid development of the whole plant.

ROSES FOR HOUSE FRONT (Catherine).—Two excellent varieties would be Climbing Caroline Testout and Gloire de Dijon. You could either nail the growths to the wall by means of some shreds or put in at intervals some small hooks so as just to loop the growths as they need it. We rather prefer this latter arrangement, as a Rose appears more natural when it hangs away from the wall a little and the pendulous nature of the growth induces a more abundant blooming. A good creeper for the side of the house would be *Chamaecytisus montana*, white Jasmine or Wistaria

ROSE FOLIAGE DISEASE (Lady Beaumont).—The Roses have been badly infested with Rose slugworm. It has been very prevalent this year, and might easily have been discovered beneath the foliage. The slugworms are very small, of a pale yellowish green colour. They can easily be killed by spraying the bushes with nicotine wash, repeating it at frequent intervals. In winter, remove the surface soil of all the beds very carefully and have it burnt, placing fresh soil on the roots, as the larvae, when mature, fall to the ground and pupate in the soil in small oval cocoons.

THE GREENHOUSE.

PRICE OF BEGONIA METALLICA (T. H. S.).—This Begonia cannot by any means be termed a scarce variety. If it is a well-furnished plant in good condition it should be worth 5s.

LEONTICE (W. P. W.).—There are three or four species of Leontice, but they are tuberous, not bulbous, plants. The flowers of the different kinds are of a yellow or yellowish colour, borne several together on a spike from 6 inches to 1 foot in height. They are hardy in a well-drained soil, but flower so early in the year that they are most satisfactory when grown under glass.

THE GREENHOUSE WINTER SWEET (C. W. K.).—This plant, known by the scientific names of *Acokanthera spectabilis* and *Toxicophlœa*, comes from the northern portion of Natal, and consequently requires more heat than South African plants in general. It thrives in the coolest part of the stove or in an intermediate house; that is to say, a structure with a minimum night temperature of 50°, rising during the daytime and increasing as the days lengthen and the sun gains power. A compost made up of loam, peat and sand will suit the *Acokanthera*. As your plants are in small pots, we should not advise you to shift them until the month of February, as the roots will by then be regaining their normal activity and soon take possession of the new soil. If you desire to grow your plants in the form of bushes, they must have the growing points pinched out several times during their earlier stages, for the *Acokanthera* is naturally of a somewhat straggling habit of growth. It does well trained up the glass at the end of a warm structure. The flowers, borne in dense axillary clusters, usually during the winter months, have obtained for it the name of the Winter Sweet, which, by the way, is also applied to a hardy shrub—*Chimonanthus fragrans*. You say nothing as to the treatment your plants have received, hence we cannot indicate the weak spot in their culture.

FRUIT GARDEN.

QUINCES SPLITTING (A. P. Sussex).—The rotting of the quince is due to there being a crack into which rot-producing fungi could gain an entrance. It does not appear that the cracking was in any way due to the fungus, but probably the attack of the latter began after the fruit was picked. There is nothing in the fruit to suggest the cause of the cracking, but probably the roots got dry in the summer, and as a consequence the skin rather set, while the wet weather we have experienced since August caused it to attempt to swell so rapidly that the skin burst. We do not think the wood-ashes had anything to do with the trouble.

BLACK CURRANTS AND BIG-BUD (Forfar). The big-bud disease among Black Currant bushes has become all too common, not many gardens being free from it. It seems a hopeless task to try to exterminate it; so many have tried, and all have failed as far as we know. The best we can hope to do is to keep it more or less in subjection, and the only way of doing this is the method you propose to adopt with your young Boskoop Giant tree, namely, pick off the diseased buds and burn them and the twigs together. There is one comfort we can take to heart in the matter, namely, that trees (and we have noticed old trees especially) seem to go on bearing good crops of fruit in spite of the disease.

MISCELLANEOUS.

IMPROVING THE SOIL (A. E.).—Remove the sardine tins, broken bottles and crockery as completely as possible, and give a good dressing of stable manure and dig in. As a general manure you may mix (at the rate per square yard) 1oz. of sulphate of potash, half an ounce of sulphate of ammonia, half an ounce of superphosphate, and fork in lightly in spring. Nitrate of soda may be used sparingly for special cases in which it is desired to get plants to grow more vigorously.

TENCH WEED (G. K. Sussex).—The weed in your lake is the Tench Weed (*Potamogeton natans*). The only way to eradicate it is to keep it pulled out. If it were possible to clean the lake out entirely, that, by removing the mud, would go a long way towards destroying the weed. The lower kinds of plant-life, such as Alga, may be destroyed by adding copper sulphate to the water at the rate of one part to 750,000 to 1,000,000 parts of water, but such weeds as the Tench Weed would require a much stronger solution, and one which would kill all kinds of water plants and fish at the same time.

USEFUL INSECTICIDES (G. S.).—The best wash for aphids on Roses or anything else is one of the Tobacco washes, which may be made by steeping half a pound of Tobacco leaf in water for two hours and diluting to ten gallons; but it is not cheap. We have found Quassia and soft soap almost equally effective, so long as it is used when the insects first make their appearance. It is made by boiling gently 1lb. of Quassia chips in water for a couple of hours, dissolving half a pound of soft soap in the water

and diluting the whole to ten gallons. This may be used indoors, but we know of no better dip than the one made by kneading flowers of sulphur in a handful of soft soap and dissolving the mixture in one and a-half gallons of hot water. This is excellent for sponging or dipping Palms and similar plants.

OIL-STOVE FOR HEATING A TOMATO-HOUSE (E. W. A.).—If you object to pipes in the house, you cannot do better than have a stove such as the one you refer to. These and similar stoves are very useful, and serve the purpose well if they are kept clean and filled late every night, so that the wick can be left burning level for the night. Several firms advertise lamps in THE GARDEN from time to time, which heat short lengths of pipes filled with water and fixed to the top of the lamp. For a long, narrow house, such as yours, a lamp of this kind would give a more even heat throughout the structure.

INJURY TO CARNATIONS AND GRAPES (Enquirer).—The leaves of the Carnations are badly attacked by the fungus *Heterosporium echinulatum*. This fungus is always more prevalent, like the rust, in houses where the atmosphere is moist than where it is dry, and we should recommend you to keep the night temperature up to about 54°, to keep the air dry, and to ventilate on all suitable occasions. The Grapes sent are not only of poor colour, but also of poor size, and the spotting on them appears somewhat like that produced by red spider, but may be due to mealy bug. Is the house devoted only to Grapes? If not, they are probably interfered with by the other occupants. Perhaps, also, the temperature has been too low or variable. They certainly ought to be going to rest now. The fact that you have found shanking to occur is clear evidence that there is something wrong with the border, and until that is attended to it is not at all likely that you will be able to get good Grapes. In all probability the drainage of the border is defective, and very likely also there is a deficiency of potash, which should be made good by manure.

CARNATIONS SPLITTING THEIR CALYCES (E. M. B.).—Carnations split their calyces from many and various causes, lack of cultivation, overfulness of the flower, short and ill-shaped pods, being some of the primary causes. Some burst habitually because of their short, pear-shaped pods, i.e., those which are unduly large at the top and small at the base. Such as these, unless they possess some special quality of colour or fragrance, are not worth tolerating, seeing there are so many varieties of all sections to-day without the defect of which you complain. The flower that opens perfectly when rightly cultivated is that having a long, cylindrically-inclined calyx of pod, and from which the petals rise in regular order. We remember the late Mr. James Douglas, who raised thousands of seedling Carnations each year, saying that if three dozen of such a lot were good enough to merit a trial a second year, and one dozen sufficiently good in that trial to rank as first-rate flowers, he was perfectly satisfied. In so large a lot of seedlings we have seen scores that would have been welcome thirty years ago; but to-day, so rigid is the selection and so good the existing strains of these flowers, there is only room for the very best.

NAMES OF PLANTS.—Alice Gill.—1, *Tradescantia crassicaulis*; 2, *Lotus Bertholetii*.—W. E.—1, *Cypripedium insigne* variety; 2, *C. Niobe*; 3, *C. arthurianum*; 4, *C. leucanum* variety; 5, probably *Oncidium flexuosum*.

THE EDITOR'S TABLE.

Outdoor Flowers from Tunbridge Wells.

A lady who signs herself "J. M. N." sends a most interesting collection of flowers, gathered from the open, with the following letter: "We are sending you a few flowers for your table, all picked from the open borders in the garden—*Daphne fioniana*, *D. Dauphinii*, *Desfontainea spumosa*, *Fuchsia microphylla*, *Grevillea sulphurea*, *Humea elegans*, *Leptospermum scoparium*, *Lithospermum rosmarinifolium* and *Parochetus communis*. The two *Daphnes* have been in constant bloom since April, and the *Grevillea* has had some flowers on it ever since October, 1912. We planted the *Parochetus* as a small plant on the north side of the rockery in June, and it is now a large mass of leaf and bloom, covering a space of 14 feet. Our *Leptospermum* was planted several years ago in one of the most exposed parts of the garden. It is now 10 feet 7 inches high, and there is hardly a month in the year in which there is no blossom on it. In July this year it was perfectly white with flowers all over it. It seeds itself freely in the gravel walks and borders near the shrub. The *Lithospermum* flowers are such an exquisite blue. We hope they will not all have fallen off by the time they reach you."
